There are two routes by which an embolus could pass directly to the left from the right side of the heart through a patent foramen ovale or through an opening in the interventricular septum Pressure is higher in the left than in the right auricle, and the foramen ovale is usually guarded, on the left side of the interauricular septum, by a flap-valve The head of pressure on the left side is sufficient to keep the flap closed and so to ensure the competence of the valve From the mechanical point of view an alteration of pressure between the two sides of the heart is required to destroy the competence of the valvular foramen ovale, thus a rise in the right auricular pressure and a fall in that of the left auricle would cause the valve to open Haggart and Walker (1923) found that a partial occlusion of the pulmonary artery in cats caused a rise of pressure in the right side of the heart, accompanied by a fall of pressure in the left side This mechanism has been supposed to operate when an embolus lodges in the pulmonary artery, and Thompson and Evans have advanced three criteria for the production of paradoxical embolism

1 At least a third of the diameter of the pulmonary artery must be occluded by an embolus less than this is not sufficient to alter the pressures materially, while occlusion of more than a half results in immediate death

2 A second embolus must shortly follow the first and appear in the right auricle

3 The second embolus must be small enough to pass through the foramen ovale, now rendered patent through alteration in intracardiac pressure

In the case here described there was no clinical evidence of a pulmonary embolus, physical examination of the lungs was normal, respiration-rate unaltered, tempera ture normal, there was no cough and no sputum, and a radiogram of the chest, when the patient was well enough to have one taken, was normal Of Thompson and Evans's 5 cases of paradoxical embolism, only 2 showed evidence of pulmonary embolus, and it seems that though this occurrence is possibly a mechanical necessity in the cases of valvular foramen ovale, it is not essential to paradoxical embolism Two other possibilities exist First, a widely patent foramen ovale could allow the passage of an embolus without previous pressure changes In 1100 consecutive autopsy records examined by Thompson and Evans at the London Hospital, patency of the foramen ovale was found in 35% (29% up to 2 cm and 6% up to 7 cm) In a further 24 cases dying from pulmonary embolism, and found at autopsy to have a patent foramen ovale, there was no evidence of paradoxical embolism Sir Thomas Lewis (1934) stated that patency (which he distinguished from mere persistence by the size of the aperture) of the foramen ovale was very rare, neither condition he said gave rise to signs It seems possible that a widely open foramen, giving rise to no physical signs, could transmit an embolus in the absence of pressure changes

A second theory put forward as a possible alternative, is that the embolus arrives in the right auricle, coils up over the tricuspid valve and blocks it sufficiently to cause the momentary rise in pressure necessary to force open the valve guarding the patent foramen ovale. The embolus is then swirled through the foramen to the left heart and so to the systemic circulation the tricuspid valve acts normally again, the foramen ovale flap-valve closes and the pressures are restored to normal I do not suggest that these alternatives are mutually exclusive, but that either may be in operation according to the state and size of the foramen ovale

Diagnosis can never be certain, but Thompson and Evans stated that "If a patient the subject of venous thrombosis develops cerebral embolism and if in such a patient there is no clinical evidence of any cardiovascular disease present then it may be justifiable to assume that the embolus is of the paradoxical variety" In my case there were no clinical or radiological signs of cardiovascular abnormality. The circulation-rate was estimated with the object of demonstrating if possible, the existence of a patent foramen ovale The arm-to-tongue method was employed, using Suprachol The time was 12 sec the normal for young men being 12–16 sec Although the result was inconclusive it was at least at the rapid extreme of normal range

The differential diagnosis lay between paradoxical embolism and thrombophlebitis migrans Ryle (1936) says that thrombophlebitis migrans is never due to varicosity, that it is essentially migratory affecting multiple small lengths of superficial veins, and is accompanied by fever hæmoptysis, pleurisy and hæmaturia may also occur Paradoxical embolus, therefore, was confidently diagnosed in this case Recovery was virtually complete I can find no record of a previous case of paradoxical cerebral embolism which recovered, with the exception of case 1 in Thompson and Evans's series, which they described as unique

SUMMARY

A case of paradoxical cerebral embolism is described, in a young man who recovered completely

There was no evidence of previous pulmonary embolus

The embolus may have reached the systemic circulation either by passing directly through a widely patent foramen ovale, or (if the patent foramen was of the valvular type) by causing temporary obstruction to the tricuspid valve so that the pressure in the right auricle rose above that in the left auricle, and the embolus was swept through the foramen

I wish to thank Dr L C Martin, who had charge of the case, and Dr Leslie Cole who estimated the circulation-rate

ISOAGGLUTININ CHANGES
AFTER TRANSFUSION OF INCOMPATIBLE BLOOD AND SERUM

P L MOLLISON, M B CAMB M R C P
I MAUREEN YOUNG, B SC
(*South-west London Blood-supply Depot*)

LITTLE attention has so far been paid to serological changes in the recipient after the transfusion of incompatible blood There are only 3 recorded cases in which such changes have been noted

Ro (1937) reports the case of a patient of group O who received 500 c cm of group A blood Although preliminary cross-matching showed no agglutination of the donor's cells by the recipient's serum, when the test was repeated with serum obtained two days after the transfusion agglutination occurred up to a dilution of 1/20 At the end of five weeks the agglutinating power of the recipient's serum for A cells had increased further and agglutination occurred in a dilution of 1/200. Four weeks later the titre had fallen to 70 (the titre being expressed as the reciprocal of the greatest dilution in which agglutination is noted) Ro suggests that the recipient's serum contained only a hæmolysin for A cells before the transfusion and that the introduction of A cells stimulated the production of an agglutinin In any case, it seems clear that the agglutinin titre rose rapidly during the period following the transfusion

Wiener (1941) has published details of 2 cases, both of which had been referred to previously (Wiener 1939) The first patient, of group O, received 500 c cm of group B blood Six hours after the transfusion, which was followed by a rigor and hæmoglobinuria but no serious sequelæ, it was observed that whereas the titre of the anti A isoagglutinin was 32, that of the anti B agglutinin was as low as 1 Further estimations were made at short intervals, and it was found that while the titre of the anti-A isoagglutinin remained constant, that of the anti B agglutinin rose steadily, reaching a peak, at the thirteenth day, of 512 The same figure was found when the serum was re titrated on the twenty fourth day after the transfusion. The other case was less closely observed Six days after the transfusion of incompatible blood (of group AB, the patient belonging to group A), it was found that the titre of the anti-B agglutinin was 128, and eight days later 256 It is concluded that these changes represent an absorption of isoagglutinin by the injected agglutinogen followed by an immune response to the foreign agglutinogen

In only one of these 3 cases were frequent titrations of the recipient's serum carried out and in that observations were only extended up to the twenty-fourth day after transfusion. It may therefore be of interest to record the following case in which, after the transfusion of incompatible blood the isoagglutinins in the serum of the recipient were repeatedly titrated and the changes were followed for some months The results obtained are in substantial agreement with those of Ro and Wiener, but changes in the "other agglutinin" were also found —i e after the transfusion of group B blood to a person of group O not only was the titre of the anti-B agglutinin affected but also that of the anti-A agglutinin These changes were traced to the use of a serum of group different from that of the patient

CASE-RECORD

A married woman aged 32, was admitted to hospital at 1 A M on Sept 16 1940 half an hour after receiving injuries caused by a high-explosive bomb The injuries were mainly due to falling masonry and included fractures of both legs She was found to be "shocked" and was treated with warmth, morphia and the transfusion of blood and plasma After receiving 540 c cm of citrated stored blood 3 days old (equal to 360 c cm whole blood) and 250 c cm of pooled plasma, she improved sufficiently for the doctors in charge to leave her for the night Next morning it came to our notice that the bottle of blood that had been given was not of group O, as had been assumed, but of group B The patient was visited by us for the first time at 10 A M some eight hours after the transfusion had been given She was then in a very poor condition Her lips and nails were ashen grey and her skin very cold No pulse was palpable at either wrist or over either brachial artery and no sounds could be heard at the latter site on auscultation We were told that although no untoward symptoms had occurred during the transfusion, no great improvement had followed, the patient's condition had deteriorated since, particularly during the last three hours

After a preliminary intravenous injection of 150 c cm of 3% sodium citrate, 1500 c cm of pooled citrated plasma, 100 c cm of four times normal reconstituted serum and 2 pints of citrated blood (group O) were transfused The clinical condition improved steadily throughout the transfusion and four hours from the beginning of this treatment, when all but the last 500 c cm of blood had been given, the blood pressure was 116/80 mm Hg and the extremities had become quite warm

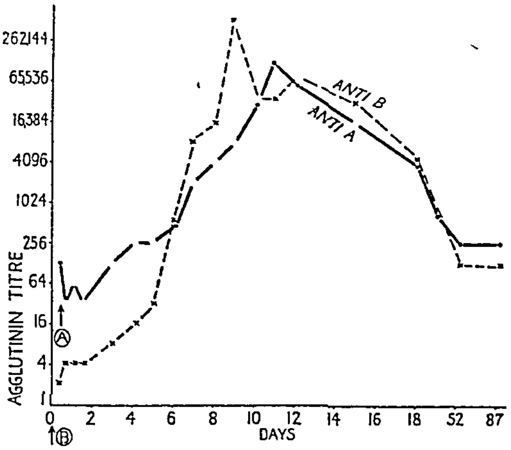

Fig 1—Changes in titre of serum isoagglutinins after transfusion of (1) group B blood (at B), (2) concentrated serum of group A (at A) Recipient was group O

A quarter of an hour after the preliminary intravenous injection of alkali the patient was catheterised and 95 c cm *of blood stained urine was* withdrawn The urine was slightly acid to litmus and had probably all been formed many hours previously, since the blood pressure was still unrecordable at this time Very many red cells and some leucocytes but no casts were found in the centrifuged deposit of this specimen, the supernatant fluid only contained 0 7% hæmoglobin (Haldane) The patient was catheterised again at 12 45 P M, when 170 c cm of urine was withdrawn, this was neutral to litmus On centrifuging, it was apparent that the red colour was due almost entirely to red blood-cells, the supernatant fluid containing only a trace of hæmoglobin as measured by the benzidine test

A venous sample was first obtained eight hours after the initial transfusion and the findings were hæmoglobin 66%, serum bilirubin 2 mg per 100 c cm serum proteins 4 3%, blood urea 55 mg per 100 c cm, blood group O Microscopical examination of a suspension showed fair sized agglutinates which were not increased by the addition of anti A or anti B serum A sample of serum was obtained at the same time and titrated with A and B cells from the donors normally used by this laboratory The technique employed is that recommended by Taylor and Prior (1938), the end point is read microscopically and clumps of 3–5 cells are taken as evidence of agglutination The titre of the anti A agglutinin was 128 and of the anti B only 2 (see fig 1) At 12 45 P M, after the patient had received 1500 c cm citrated plasma and 100 c cm of four-times normal serum, a second venous sample was taken and examined The hæmoglobin had fallen to 42% while the plasma proteins had risen to 4 7% The serum bilirubin was 2 5 mg per 100 c cm, and the blood urea 45 mg per 100 c cm (see fig 2) Microscopical examination showed rather bigger agglutinates than in the first smear The titre of the anti A agglutinin had fallen to 32, while that of the anti B had risen slightly to 4

After the further transfusion of two bottles of blood and 150 c cm of 3% citrate, another venous sample was obtained (5 20 P M) The hæmoglobin was now 49%, serum bilirubin 1 8 mg per 100 c cm, serum proteins 4 9% and blood urea 75 mg per 100 c cm The titre of the anti-A agglutinin was 64 and of the anti-B again 4

From the time when the patient was first seen by us, an attempt was made to measure the fluid intake and the urinary output During the first twenty four hours 3000 c cm of lemon squash containing 35 g of potassium citrate was given (as advised by Bushby and others 1940), and 2000 c cm of the same mixture was given during the subsequent twenty four hours A rather incomplete record of the fluid intake and urinary output was kept, but it was clear that there was a large negative water balance up to the eighth day, although the urinary output never fell to really low levels

The patient was visited again on the morning of the 17th, some thirty hours after the incompatible transfusion Her clinical condition was surprisingly good She was lucid and not in pain Her skin looked faintly yellow She had been catheterised at 5 A M, and 70 c cm of urine had been withdrawn This specimen contained albumin and was to litmus The sediment contained many red blood cells no casts The supernatant fluid contained only a trace hæmoglobin On this occasion the temperature was 99° F pulse rate 120 and blood pressure 116/80 mm Hg The bloo still contained agglutinates, the blood-urea had risen t 101 mg per 100 c cm, the serum bilirubin to 3 2 mg per 100 c cm and the serum proteins to 5 1% The titre of the anti A isoagglutinin was 32, that of the anti B agglutinin still 4

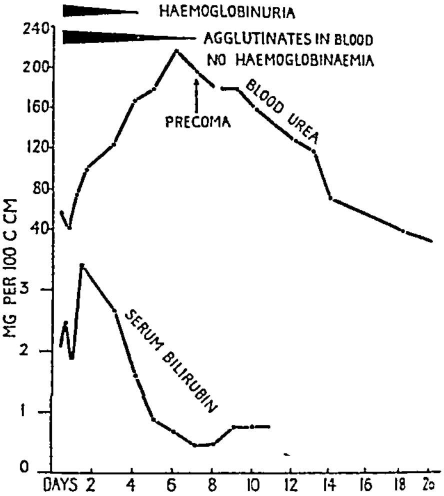

Fig 2—Findings after incompatible transfusion

On the 18th the patient was better, although the blood pressure was 136/102 mm Hg and the blood urea 126 mg per 100 c cm The serum bilirubin had fallen a little (2 7 mg per 100 c cm) A smear of the blood showed only a few small agglutinates The titre of the anti B isoagglutinin had risen to 8 and that of the anti A isoagglutinin to 128 The urine was alkaline to litmus, and the sediment contained a few red blood cells and pus and epithelial cells, but once more no casts During the past twenty four hours she had passed only 10–20 oz of urine, compared with a fluid intake of 80 oz

Until the 22nd (the 7th day) the patient appeared to improve steadily, despite a consistently raised diastolic pressure and a steadily mounting blood-urea During this period agglutinates were found in the blood but they became progressively smaller and actually were last seen on the 23rd From the 18th onwards the titre of both anti A and anti B isoagglutinins rose steadily, and, as will be seen from fig 1, reached very great heights during the period Sept 24–27 (9th to 12th days) Between Sept 23 and Oct 11, when the titrations were read, it was noted that hæmolysis occurred in the first or first and second dilutions with both A and B cells

On Sept 23 the patient was much worse She was very drowsy, her respirations were deep and there was a heavy brown fur on the tongue she was considered to be in precoma The blood-pressure was 150/100 mm Hg On this and the subsequent two days the patient was made to sweat profusely by giving Dover's powder and aspirin and heating her with electric blankets, &c Whether as the result of the sweating or not, she was much better on the 24th, and the urinary output increased from this day onwards On the 25th the improvement was maintained and the blood pressure had fallen to 136/80 mm Hg From this time onwards, recovery was uneventful from the medical point of view

During the ten days after the transfusion, two attempts were made to perform renal function tests Neither was wholly satisfactory, but both revealed an unequivocal degree of impairment of renal function On Sept 21 the clearance wa 18% of normal and on the 26th, 30% (van Slyke) On the 26th the urine contained a trace of albumin and a few epithelial and granular casts The urea clearance test was repeated on Oct 4 and was then 50% of normal

Further examinations of the serum were made during the following months A slow reduction in the titre of both isoagglutinins was found From the abnormally high levels reached two weeks after the transfusion the titres gradually fell towards normal

DISCUSSION

The changes in the titre of the anti-B isoagglutinin will be seen to be of the same nature as those described by Wiener; they consist of an initial reduction, presumably due to an absorption by the transfused group B blood, followed by a big increase, presumably representing an immune response. The first specimen in our case was obtained eight hours after the transfusion and thus may be compared with the first specimen in Wiener's case, obtained after 6 hours. The titre of the anti-B isoagglutinin was found, as in Wiener's case, to be extremely low. Thereafter there was a steady rise in titre, and the peak was reached on about the eighth day (not before the thirteenth day in Wiener's case). The extent of the rise, however, seems to have been much greater in this case even when allowance is made for individual differences in the reading of serum titrations. Thus in our case agglutination with B cells could be detected in a dilution of 1/500,000 compared with the figure of 1/512 given by Wiener. Wiener (1941) has recently stated that with the technique that he employs the average isoagglutinin titre is only 16–32. In this laboratory, using the technique referred to above, rather higher figures are obtained (average 64–128). This difference in the normal end point is insufficient to account for the much greater rise in titre observed in our case. The slow return to a normal level is in accord with Ro's observations.

The changes in the anti-A isoagglutinin—a small initial fall followed by a large rise—at first seemed to be a non-specific response to the injection of the group B blood. Then, however, a more convincing explanation suggested itself. At the time when these observations were made, Aubert, Boorman and Dodd, of this laboratory, were engaged in confirming and extending the work of Schiff (1924), an account of their work is in the press. Schiff first demonstrated the presence of the group-specific substances in soluble form in the serum and postulated an equilibrium between the concentration of agglutinogen in erythrocytes and serum. With this fact in mind, it seemed likely that the rise in the titre of the anti-A agglutinin might have been due to the injection of group A substance in either the plasma or serum that had been transfused in the course of treatment. The plasma, however, was taken from a pool of different groups. It has been demonstrated that this plasma is virtually free of agglutinins, and it may therefore be safely assumed that it only contains traces of the corresponding agglutinogens. The serum, on the other hand, was found to be of group A and had not been pooled. Soon after we had made these observations, Aubert and his colleagues demonstrated that it was possible to produce an immune response in man to the agglutinogen contained in serum of groups A, B or AB. This latter work was carried out with Seitz-filtered human serum. Since the serum injected in our case was a four-times concentrated solution, reconstituted from dried serum * which had been Seitz-filtered before drying, we tried the effect of injecting similarly prepared serum of group A into two people of group O. The results are given in fig. 3. As will be seen, after a small fall, the titre of the anti-A agglutinin rose considerably. Thus a satisfactory explanation for the changes in the titre of the anti-A isoagglutinin in the patient who also received group B blood was reached.

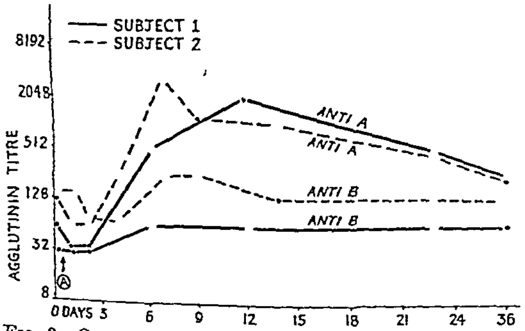

FIG. 3—Control experiments. Changes in titre of anti A agglutinins in two patients of group O after the transfusion of 100 c.cm. of four times normal concentrated human serum of group A, reconstituted from the dried product. The serum had been Seitz-filtered before being dried. Transfusions given at A.

It will be noted that the rise in titre of the anti-A isoagglutinin was also very great and considerably exceeds that of the two "controls." It also exceeds that produced by Aubert in any of his experiments (personal communication). The fact that the rise in titre of both agglutinins was so large suggests the possibility of some non-specific stimulation in each case. Aubert has noted slight changes in the anti-A agglutinin after the injection of the B agglutinogen in B serum and vice versa. Further, it is well known that the naturally occurring anti-A or anti-B agglutinin in the serum of some rabbits is often much increased after the injection of OM or ON cells to produce anti-M or anti-N sera. Davidsohn (1938) has pointed out that the isoagglutinin titre of human serum is increased after the induction of serum sickness. In view of these observations it seems reasonable to suppose that some reciprocal non-specific stimulation may have occurred between the one antibody response and the other.

Before this explanation for the changes in titre of the anti-A isoagglutinin had suggested itself, the recipient's serum was tested for the presence of anti-M and N agglutinin, in case their production had been stimulated. No anti-M or anti-N antibodies were found.

As has been mentioned, agglutinates were detected in the recipient's blood-stream up to the seventh day after transfusion. Only until the day after the transfusion, however, were these agglutinates fair-sized. From this day until the seventh only a few small agglutinates persisted, but even on the seventh day a few clumps of five cells were seen. No clumps could be detected on the eighth day or later. Burnham (1930) found some donor cells remaining in the recipient's blood stream on the third day, but none on the sixth day, after the transfusion of incompatible blood. Wiener and others (1941) in another case found that all but a few of the incompatible cells had been eliminated two days after transfusion.

The rise in serum-bilirubin is a typical finding and is too great to be attributable to the transfusion of stored blood per se. In our experience the transfusion of blood previously stored for three days with a citrate-saline-glucose solution normally leads to only small transient increases in the serum-bilirubin of the recipient.

From the clinical aspect the case adds nothing to existing knowledge of the syndrome of renal insufficiency after the transfusion of incompatible blood, particularly because of the complicating factor of severe injury. As Grant and Reeve (1941) have recently pointed out, there is as yet no precise knowledge of the circumstances in which renal function is disturbed in air-raid casualties.

The passage of many red cells in the urine may have been due to a contusion of the left kidney, since that side of the body was very bruised.

It is interesting to note that there was no immediate reaction to the transfusion—540 c.cm. of citrated stored blood (containing 360 c.cm. whole blood) was transfused in approximately thirty minutes, but no untoward effects were noted. The temperature, however, was not recorded. Others have noted that the transfusion of incompatible blood is not necessarily accompanied by any obvious immediate reaction (Grove and Crum 1930, Wiener and others 1941).

The progress to uræmia and then to recovery was very similar to that of some of the cases described by Bordley (1931), and the final outcome was in close accord with his observation that no patient receiving less than 350 c.cm. of incompatible blood died.

Knowledge of alterations in the titre of the affected agglutinin, after the transfusion of incompatible blood, has important practical applications. First, if after a hæmolytic reaction, cross-matching is repeated with serum obtained from the recipient within a day or two of transfusion, a false negative result may be obtained owing to the temporary suppression of the agglutinin concerned. Secondly, when the donor cannot be traced, serial titrations of the recipient's serum will decide whether or not the blood given contained an incompatible agglutinogen. Thirdly, cross-matching repeated on the

---

* From the Medical Research Council's serum drying unit at Cambridge.

symptoms had occurred during the transfusion, no great improvement had followed, the patient's condition had deteriorated since, particularly during the last three hours

After a preliminary intravenous injection of 150 c cm of 3% sodium citrate, 1500 c cm of pooled citrated plasma, 100 c cm of four times normal reconstituted serum and 2 pints of citrated blood (group O) were transfused The clinical condition improved steadily throughout the transfusion and four hours from the beginning of this treatment, when all but the last 500 c cm of blood had been given, the blood pressure was 116/80 mm Hg and the extremities had become quite warm

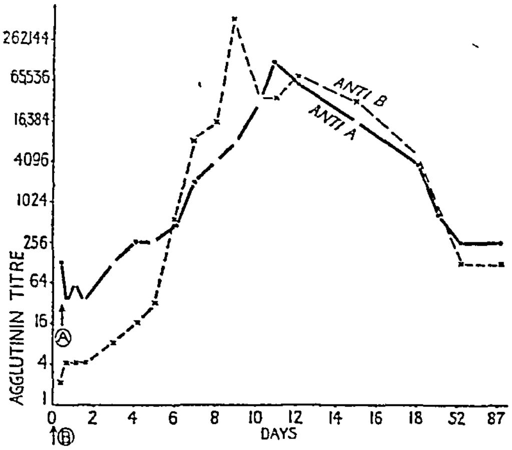

Fig 1—Changes in titre of serum isoagglutinins after transfusion of (1) group B blood (at B), (2) concentrated serum of group A (at A) Recipient was group O

A quarter of an hour after the preliminary intravenous injection of alkali the patient was catheterised and 95 c cm of blood stained urine was withdrawn The urine was slightly acid to litmus and had probably all been formed many hours previously, since the blood pressure was still unrecordable at this time Very many red cells and some leucocytes but no casts were found in the centrifuged deposit of this specimen, the supernatant fluid only contained 0 7% hæmoglobin (Haldane) The patient was catheterised again at 12 45 P M, when 170 c cm of urine was withdrawn, this was neutral to litmus On centrifuging, it was apparent that the red colour was due almost entirely to red blood-cells, the supernatant fluid containing only a trace of hæmoglobin as measured by the benzidine test

A venous sample was first obtained eight hours after the initial transfusion and the findings were hæmoglobin 66%, serum-bilirubin 2 mg per 100 c cm serum proteins 4 3%, blood urea 55 mg per 100 c cm, blood group O Microscopical examination of a suspension showed fair-sized agglutinates which were not increased by the addition of anti A or anti B serum A sample of serum was obtained at the same time and titrated with A and B cells from the donors normally used by this laboratory The technique employed is that recommended by Taylor and Prior (1938), the end point is read microscopically and clumps of 3–5 cells are taken as evidence of agglutination The titre of the anti A agglutinin was 128 and of the anti B only 2 (see fig 1) At 12 45 P M, after the patient had received 1500 c cm citrated plasma and 100 c cm of four times normal serum, a second venous sample was taken and examined The hæmoglobin had fallen to 42% while the plasma proteins had risen to 4 7% The serum bilirubin was 2 5 mg per 100 c cm, and the blood urea 45 mg per 100 c cm (see fig 2) Microscopical examination showed rather bigger agglutinates than in the first smear The titre of the anti A agglutinin had fallen to 32, while that of the anti B had risen slightly to 4

After the further transfusion of two bottles of blood and 150 c cm of 3% citrate, another venous sample was obtained (5 20 P M) The hæmoglobin was now 49%, serum bilirubin 1 8 mg per 100 c cm, serum proteins 4 9% and blood urea 75 mg per 100 c cm The titre of the anti-A agglutinin was 64 and of the anti-B again 4

From the time when the patient was first seen by us, an attempt was made to measure the fluid intake and the urinary output During the first twenty four hours 3000 c cm of lemon squash containing 35 g of potassium citrate was given (as advised by Bushby and others 1940), and 2000 c cm of the same mixture was given during the subsequent twenty-four hours A rather incomplete record of the fluid intake and urinary output was kept, but it was clear that there was a large negative water balance up to the eighth day, although the urinary output never fell to really low levels

The patient was visited again on the morning of the 17th, some thirty hours after the incompatible transfusion Her clinical condition was surprisingly good She was lucid and not in pain Her skin looked faintly yellow She had been catheterised at 5 A M, and 70 c cm of urine had been withdrawn This specimen contained albumin and was to litmus The sediment contained many red blood cells no casts The supernatant fluid contained only a trace hæmoglobin On this occasion the temperature was 99° F pulse rate 120 and blood pressure 116/80 mm Hg The b still contained agglutinates, the blood-urea had risen to 101 mg per 100 c cm, the serum bilirubin to 3 2 mg per 100 c cm and the serum-proteins to 5 1% The titre of the anti-A isoagglutinin was 32, that of the anti B agglutinin still 4

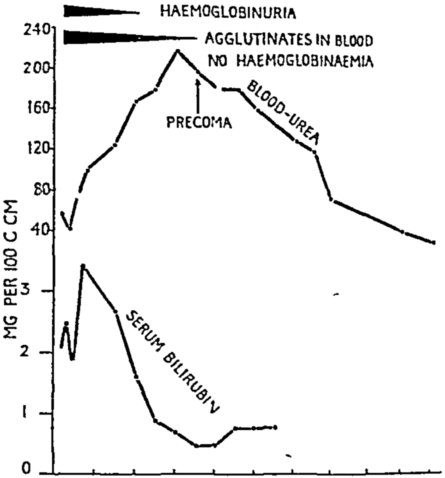

Fig 2—Findings after incompatible transfusion

On the 18th the patient was better, although the blood pressure was 136/102 mm Hg and the blood urea 126 mg per 100 c cm The serum bilirubin had fallen a little (2 7 mg per 100 c cm) A smear of the blood showed only a few small agglutinates The titre of the anti B isoagglutinin had risen to 8 and that of the anti A isoagglutinin to 128 The urine was alkaline to litmus, and the sediment contained a few red blood cells and pus and epithelial cells, but once more no casts During the past twenty-four hours she had passed only 10–20 oz of urine, compared with a fluid intake of 80 oz

Until the 22nd (the 7th day) the patient appeared to improve steadily, despite a consistently raised diastolic pressure and a steadily mounting blood urea During this period agglutinates were found in the blood but they became progressively smaller and actually were last seen on the 23rd From the 18th onwards the titre of both anti A and anti B isoagglutinins rose steadily, and, as will be seen from fig 1, reached very great heights during the period Sept 24–27 (9th to 12th days) Between Sept 23 and Oct 11, when the titrations were read, it was noted that hæmolysis occurred in the first or first and second dilutions with both A and B cells

On Sept 23 the patient was much worse She was very drowsy, her respirations were deep and there was a heavy brown fur on the tongue she was considered to be in precoma The blood-pressure was 150/100 mm Hg On this and the subsequent two days the patient was made to sweat profusely by giving Dover's powder and aspirin and heating her with electric blankets, &c Whether as the result of the sweating or not, she was much better on the 24th, and the urinary output increased from this day onwards On the 25th the improvement was maintained and the blood pressure had fallen to 136/80 mm Hg From this time onwards, recovery was uneventful from the medical point of view

During the ten days after the transfusion, two attempts were made to perform renal function tests Neither was wholly satisfactory, but both revealed an unequivocal degree of impairment of renal function On Sept 21 the clearance was 18% of normal and on the 26th, 30% (van Slyke) On the 26th the urine contained a trace of albumin and a few epithelial and granular casts The urea clearance test was repeated on Oct 4 and was then 50% of normal

Further examinations of the serum were made during the following months A slow reduction in the titre of both isoagglutinins was found From the abnormally high levels reached two weeks after the transfusion the titres gradually fell towards normal vided between ligatures. There was no wound in the lung. d the pericardium was now inspected—it was tense and lue—cardiac pulsations were only barely palpable on its urface and no wound could be found. An exploring needle as inserted and blood was withdrawn. The pericardium as accordingly opened and about ½ pint of blood escaped ith a rush; the anæsthetist immediately reported a considerable improvement in the quality of the pulse and the eart could be seen beating freely. In spite of careful earch no bleeding point could be seen on the surface of the eart or on the pericardial walls and it was decided to close he chest. The pericardium, incised as it was for about 3 in., was left wide open and the pleura was drained. The chest was now closed. One pint of blood was given on the patient's return to the ward.

The next day the man's condition was fairly good, but his mental state was unsatisfactory. About 10 oz. of blood-stained fluid had drained from the tube when the patient pulled it out and it could not be reintroduced. Repeated aspirations were done and a fortnight later an empyema was drained under local anæsthesia. By the end of October the patient was in a poor way; he had air hunger, his respirations were laboured, the temperature was swinging and the pulse-rate was 140. Radiographs showed the pericardial shadow to be greatly enlarged in all diameters, and on screening restricted cardiac pulsations were seen. A diagnosis of suppurative pericarditis was made. On Oct. 29, 1938, pericardiotomy was done under local anæsthesia. An incision 3 in. long and parallel with the left lower border of the chest was made, beginning at the chondroxiphoid junction and extending downwards and laterally. The 7th left costal cartilage was removed and the perichondrium deep to it cut away. This exposed the internal mammary artery which was divided between ligatures. Dissection was carried out in the chondroxiphoid angle and the surface of the pericardium, tense and pale, was found. Owing to the position of the incision there was no risk of damage to the left pleura. The pericardium was opened and a profuse flow of thick pus came out in jets synchronous with the heart beat. A finger was inserted into the pericardium and "bread and-butter" adhesions, such as can be found in old empyemata, were felt and separated; more pus escaped. A drainage tube was placed down to the pericardium and the patient was nursed sitting upright to facilitate drainage; 2 pints of blood were given immediately. Saline irrigations carried out twice daily allowed a profuse discharge of pus to escape. The temperature settled and the general condition improved. A pure streptococcal culture was obtained from the pus and sulphanilamide was given to control the infection. The patient was discharged to a convalescent home on Dec. 14, 1938. On Nov. 8, 1939, he returned for incision of an abscess at the site of the original wound. This cleared up without any trouble. He had been on full work for the last 8 months as a packer in a furniture factory and had noticed no ill effects as a result of his pericarditis.

THORACO-ABDOMINAL WOUND PENETRATING THE RIGHT VENTRICLE

CASE 4.—A coloured man, aged 25, was admitted on Nov. 12, 1938, to the Groote Schuur Hospital suffering from a stab wound in the left side of the chest, through which 3 in. of omentum projected. It was thus evidently a thoraco-abdominal injury. The patient was in good condition and operation was undertaken 2 hours after admission. Under open ether anæsthesia, an incision in the 7th interspace about 10 in. long with its centre surrounding and excising the original stab, which was in the mid axillary line, was made. The chest was opened and the neurovascular bundle beneath the 7th rib was tied off after it had been under-run. A rib-spreader was introduced and the hole in the diaphragm identified. This was about 3 in. long; the spleen could be seen just under the hole. A moderate amount of blood in the pleural cavity was mopped up and the lung was pulled down, examined, and being uninjured was released and allowed to retract. At this point it was noticed that the pleura had once more filled with blood and this was traced to a wound about ½ in. long on the posterior surface of the pericardium. The pericardium was then seen to be tightly distended with blood. Since it was now obvious that a cardiac wound was present I decided to close the diaphragm and not to explore the abdomen further. The omentum was returned to the abdomen and the diaphragm was sutured with two layers of continuous no. 2 chromic catgut. The left phrenic nerve was crushed as it passed over the pericardium to paralyse the diaphragm and facilitate subsequent manipulations. The rib spreader was now removed and another incision, at right angles to the first, was made extending for about 4 in. upwards and inwards; this gave an inverted T-shaped incision. The 7th, 6th and 5th ribs were cut in the line of the supplementary incision, and their neurovascular bundles divided between ligatures; it was now possible by means of strong traction to elevate a sort of flap consisting of the chest wall, upwards and outwards. The rib spreader was reintroduced. The pericardium was now opened and about ½ pint of blood escaped. The heart was delivered into the wound, but owing to its movements it was impossible to reach its posterior surface. A no. 2 chromic suture was passed through the fibro fatty tissue at the apex and this acting as a tractor, the heart was lifted out and its posterior surface exposed. A wound about ½ in. long was found on the posterior surface of the right ventricle, close to the posterior interventricular vessels and about a third of the distance between the auriculoventricular sulcus and the apex. Two sutures of no. 1 chromic were inserted and these controlled the bleeding. The traction suture was now cut, the heart returned to its place and the pericardium was left wide open. A stab wound was made in the 8th space posteriorly and a self retaining catheter was inserted. The chest wound was then closed and the patient returned to bed.

Convalescence was uneventful. The tube was removed in 48 hours and the patient left the hospital at his own request on Dec. 2, 1938. When seen 2 months later he was fit and at work again as a labourer.

DISCUSSION

These cases show variable symptomatology. Thus, 3 were shocked on admission; the fourth, who had the thoraco-abdominal wound, was in good condition. It will be noticed that case 2, though apparently shocked on arrival at hospital, had a pulse-rate of 96 which had risen to 110 on leaving the operating table. Only in cases 1 and 2 was there any profuse external bleeding, which in case 2 came in occasional jets of dark blood; this patient had a penetrating wound of the right ventricle. In the other case of right ventricular penetration (case 4) external bleeding was not noteworthy. In case 2 the heart was saved from pressure by leakage into the pleura. Cardiac tamponade, characterised by a rapid pulse of decreasing volume with absence of an apex-beat, occurred in only one patient (case 3) in spite of the fact that the pericardium communicated with the pleural cavity; here, old adhesions seem to have prevented leakage of blood into pleura.

Every case was explored along the track of the wound. The original skin incision was excised and the wounded interspace widely opened; a view of the damage was then obtained, regardless of chest-wall structures. Ribs were sectioned with shears, costal cartilages were divided with a knife and—except in case 1—interspaces were cut across between two ligatures which transfixed and tied the neurovascular bundles. The importance of this last procedure is measured by the fact that the only death in the series (case 1) was due to a leaking intercostal vessel.

In order to suture the penetrating heart-wounds in cases 2 and 4 it was necessary to steady the heart. In case 2, a finger was placed in the hole in the heart (Elkin's manœuvre 1936). In case 4, where the stab pierced the phrenic surface of the right ventricle, a suture was passed through the fibro-fatty tissue at the apex and used as a tractor to lift the heart (Beck 1926). The chest was closed quickly by bringing the ribs together with pericostal sutures. Intercostal muscles were disregarded but parietal layers were carefully closed.

Separate drainage of the pericardium invites ascending infection. It is better to leave the pericardium opening widely into the pleural cavity and to drain the pleura with a large self-retaining catheter passed into the chest through a cannula; the end of the catheter dips under water. It is possible to get a wound of the heart without penetration of the pleura (Elkin and Phillips 1931), but even in such cases it would usually be necessary to open the left pleura in order to get sufficient exposure, so that pleural drainage would entail little extra structural damage. If case 2 had been drained, the patient might have been saved many tappings and an exploratory thoracotomy. In case 3 the adhesions appear to have prevented satisfactory pericardiopleural drainage tenth to fourteenth day after transfusion is most likely to detect the presence of a weak or atypical incompatible agglutinin, since the immune response will be maximal at this time

SUMMARY

After the transfusion of group B blood to a woman of group O, changes in the titre of the anti-B isoagglutinin were observed There was an initial reduction, followed by a rapid increase, and then a slow fall to the original level These findings confirm previous observations

Similar changes in the titre of the anti-A isoagglutinin were also found These changes almost certainly represent a response to the injection of the A agglutinogen contained, in soluble form, in the group A serum transfused in the course of treatment

We are grateful to the medical officers of the hospital concerned for allowing us access to their patient and to Dr O M Solandt, then director of this depot, for helpful criticism

STAB WOUNDS OF THE HEART AND PERICARDIUM

FOUR CASES WITH THREE RECOVERIES

THEODORE SCHRIRE, M B CAPE TOWN, F R C S
SURGICAL REGISTRAR AT THE GROOTE SCHUUR HOSPITAL, CAPE TOWN

IT has been our practice to explore and do an open thoracotomy on all consenting cases of penetrating wounds of the chest admitted to our beds at the New Somerset and later the Groote Schuur Hospitals Experiences in a series of 17 cases since the procedure became standardised were detailed in a previous paper (Schrire 1940) In this report 4 cases of penetrating wounds of the pericardium and 2 of perforation of the right ventricle are described

WOUND OF THE SURFACE OF LEFT VENTRICLE

CASE 1 —A coloured man, aged 36, was admitted to the New Somerset Hospital on March 26, 1936, with a stab wound of the chest received in a drunken brawl an hour before admission The knife had entered the left 6th interspace 1 in outside the nipple line and the wound was bleeding profusely, the patient was cold and breathless Morphine, gr ¼, was given immediately and the wound was temporarily plugged with dry gauze After an hour he had recovered sufficiently from his shock to be operated on Anæsthesia was induced with chloroform and ether and continued with ether The wound was excised and the interspace opened up, to increase the exposure, the costochondral cartilages of the 5th and 6th ribs were divided and a rib retractor was inserted The lung had escaped injury and a wound, ¾ in long, was seen in the pericardium over the left auricle, no blood issued from it The wound was enlarged and it was then possible to see that there was a superficial slit on the surface of the left wall of the left ventricle which had divided the superficial fibres of the myocardium, there was no bleeding from this wound and it was left untouched Two interrupted sutures were then inserted to close the pericardium and the chest was closed No drain was used The patient stood the operation well His condition was satisfactory till the next day when his pulse rate began to rise and he died 24 hours after the injury Autopsy showed that death was due to hæmorrhage from the 6th intercostal artery which had bled into the pleura

PENETRATING WOUND OF RIGHT VENTRICLE

CASE 2 —A coloured man, aged 46, was admitted to the New Somerset Hospital on Feb 27, 1937, having been stabbed with a kitchen knife half an hour before admission examination in the casualty department a wound ½ in and transverse in direction, was seen 1 in inside and 1¼ above the left nipple He was much shocked The rate was 96 A probe inserted into the wound could not made to enter the thorax The pulse remained steady 2 hours, during this time occasional profuse jets of blood issued from the wound Physical examination showed a complete absence of breath sounds and dullness of the left side of the chest No heart sounds could be heard on the left side but distant sounds were found behind the lower half of the sternum With 1% procaine as a local anæsthetic an incision 4 in long was made in the line of the 5th rib and the small skin wound was excised The 5th costal cartilage was found to be severed in an oblique direction and 3 in of it and of the 5th rib were resected A hole in the pleura about 1¼ in long was found and enlarged The left lung was seen to be partially collapsed but every now and then the patient would take a deeper breath, or cough, and the lung would be forced into the wound A slit on the anterior surface of the pericardium was now seen from which dark blood welled up and overflowed into the pleura which contained about a pint The flow from the pericardium was intermittent, occurring about three times a minute The wound in the pericardium was enlarged and a hole was found in the right ventricle ½ in to the right of the anterior interventricular vessels From the hole in the heart, which was ¾ in long and transverse in direction, dark blood issued in large jets synchronous with the heart beats My left forefinger, placed in this wound, controlled the bleeding I decided to enlarge the opening in the chest wall, and, as the patient would not keep still and the hæmorrhage was under control, open ether was given Using the right hand, I prolonged the skin vertically downwards for 3 in along the left border of the sternum and divided the 6th left costal cartilage The rib spreader was now introduced and a good view of the pericardium and heart was obtained A curved needle with no 1 chromic catgut was now used to put in the first suture through the middle of the cardiac wound and this was tied fairly loosely so as to approximate, but not tear through, the wall of the ventricle Using this suture as a guy, five more interrupted sutures were inserted and the bleeding was stopped The pericardium was then closed with three interrupted catgut sutures The lung was found to have escaped injury and the pleura and chest musculature were rapidly approximated after the neurovascular bundles had been transfixed and ligated The skin was then closed No drainage was employed Once the suture of the heart itself was completed the ether was discontinued and the closure was done while the patient was recovering The patient left the table in good condition with a pulse rate of 110

Convalescence was long and trying The superficial part of the wound became infected and was treated with hot fomentations, a pleural effusion, which fortunately remained sterile, developed in the left pleura and required frequent tapping and one small exploratory operation with negative findings Several blood transfusions helped to maintain strength The patient was discharged to a convalescent home 3 months after admission He was seen a year later in good condition and was in full work

WOUND OF PERICARDIUM AND PLEURA, CARDIAC TAMPONADE

CASE 3 —A coloured man, aged 21, was admitted drunk to the Groote Schuur Hospital on Oct 3, 1938 He had been stabbed in the chest an hour before, and was cold, clammy and shocked, the casualty officer noticed that the pulse was small and rapid and the respirations shallow The wound 1 in from the right border of the sternum in the 5th interspace, did not bleed to any unusual extent Under observation, the pulse became imperceptible and his general condition steadily deteriorated while the apex beat was neither visible nor palpable Cardiac tamponade was diagnosed and the patient was operated on an hour after admission He was wildly excited and quite uncoöperative, and anæsthesia was induced with C_2E_3 and maintained with nitrous oxide, oxygen and ether The chest was opened by a vertical incision which ran parallel and 1 in lateral to the right border of the sternum, and the original wound was excised Three costal cartilages were resected to improve the exposure There was some blood in the pleural space, but owing to dense old adhesions the lung had not retracted and it was necessary to separate the adhesions by means of sharp dissection in order to get a working space, the internal mammary artery was

THE LANCET

LONDON: SATURDAY, NOVEMBER 22, 1941

REST FOR INFLAMED TISSUES

Nature's method of healing has never altered, it is our technique of how to assist her that changes. Rest has always been the most natural ally of the vis medicatrix naturæ on which all healing depends. A long line of "Menders of the Maimed" in British medicine—Hunter, Hilton, Hugh Owen Thomas and others—taught that inflamed tissue is capable of dealing with its enemies unaided if kept at rest. But there are varying degrees of rest. To lie in bed does not necessarily keep the whole body at rest, the many splints are not always effective, and any fixation by traction will exert a pull on diseased structures. There is no doubt, however, that strict local rest of the injured part is obtained by the closed-plaster treatment of infected wounds. Thomas and many others would not use plaster because they felt that it impeded the circulation in the diseased part. But a properly applied plaster supports rather than constricts the vessels of supply. The comfort of the patient in plaster is our surest proof. Muscles are tissues with high vascular demands, and, as we know from Volkmann's contracture, when there is compression of the main vessel the muscle will die long before there is skin involvement, and any shortage in its blood-supply is soon demonstrated by exquisite pain. In the resting limb the maximal blood-flow is determined to a great extent by the diameter of the larger supplying arteries. A good blood-supply, and therefore an intact major vessel, is the sine qua non of the closed-plaster method of treatment. As Trueta has urged, if the blood-supply of the limb is jeopardised either by trauma or operation, treatment in closed plaster is to be avoided. A trickling stream will provide special opportunities for the flourishing of organisms, especially anaerobic, and against these early operative interference is our most useful aid.

The theoretical basis of the closed-plaster treatment is by no means fully understood. Exactly how does a plaster prevent the spread of infection? Sampson Gamgee believed that pressure on a wound directly benefits the development of the cells in it by preventing degeneration and vacuolation; Winnett Orr ascribed a special virtue to the soft paraffin with which he packed the wound; Albee suggested that bacteriophage is produced under the plaster; and Garcia Alonso maintained that a sort of civil war among the various types of bacteria confined under the plaster prevents the domination of pyogenic organisms. Probably all these views hold something of truth, but the experimental work of Barnes and Trueta[1] offers the most likely explanation of the success of complete immobilisation. The flow of the lymph is the clue. It has long been known that the capillary endothelium of the blood-vessels is resistant to bacteria and that infection reaches the blood-stream via the lymphatic circulation. Anything that diminishes the flow in this lymph will therefore help to localise the infection, and Drinker showed and Barnes and Trueta have confirmed that if a limb is immobilised the flow of lymph almost ceases. It apparently does not cease completely for, as Cressman and Blalock[2] point out, transmitted arterial pulsations probably produce some slight movement of lymph. This movement Clark and Clark[3] describe as a "bobbing" back and forth synchronous with the heart beat or respiration, with only a sluggish forward movement. Besides the lymph-trunks, which via the glands lead to the blood-stream, the lymphatic system consists of a network of anastomosing, interlacing vessels. Thus, if there is movement, not only does the lymph carry bacteria to the lymph filters, and on rare occasions to the blood, but local spread takes place because infection is squeezed into the lymphatic meshwork. Barnes and Trueta demonstrated experimentally that manual compression of the muscles produces no increased flow in the lymph-trunks but that full joint movement does greatly increase the flow. Hence the importance of immobilising the joints above and below an infected wound. Immobilisation has, of course, other important functions. It protects the frail capillary endothelium, which tears readily and waits with pouting mouths for further organisms. A dressing with the gentlest hands is then like the tramplings of an elephant's feet. Gamgee knew the importance of support for tissues which through bruising, incision or œdema have lost their natural elastic support. Dickson Wright taught the same in the treatment of varicose ulceration, where he showed that lack of support interfered with the blood-flow and that even pressure was the surest way to get the best blood-supply and healing. Winnett Orr recognised the fragility of capillary endothelium and that is why he recommended soft paraffin. Trueta realised that, provided the limb was at rest, a multiplicity of organisms disporting themselves on the wound surface interfered but little with wound healing.

There has always been the fear of ankylosis of the associated joints when immobilisation is prolonged. For acutely inflamed joints it was even the habit in the last war to insist on the patient moving despite the exquisite pain. Over fifty years ago Thomas condemned this practice in a forcible manner when he wrote "it is as reasonable to attempt to cure a fever patient by kicking him out of bed as to benefit joint disease by wriggling at the articulation." Ogilvie[4] has said the same in discussing the treatment of wounds and sepsis of the knee-joint. He maintains that immobilisation must be continued until infection is clinically overcome, and that the joint must therefore be completely immobilised for a minimum of three weeks. The slightest movement, such as changing a plaster, will result in a flare-up, and to immobilise a knee-joint absolutely nothing less than a hip spica will do. To stretch damaged or healing tissues by early movements does not loosen them but actually results in the laying down of more and more scar tissue in the lines of strain. Where it is particularly important to avoid scar formation, as in septic

Reviews of Books

Lymphatics, Lymph and Lymphoid Tissue

Their Physiological and Clinical Significance C K DRINKER, M D, D Sc, professor of physiology, school of public health, Harvard University, and J M YOFFEY, M D, F R C S, senior lecturer in anatomy, University College of South Wales and Monmouthshire Cambridge, Mass Harvard University Press Pp 406 $4 00

THIS book, appearing at a time when the behaviour of the lymphatics is exciting a good deal of attention, records what is known and indicates what is yet unknown about the lymph and the lymphoid tissue The first half of the book describes the composition, formation and circulation of the lymph It seems clear that, while proteins and particles, including bacteria, may escape from the blood capillaries together with fluid carrying solutes, only solutes with variable amounts of fluid can return again through the capillary wall Protein molecules and particles, with the remainder of the fluid, must make their way back to the circulation by the lymphatics The conditions governing capillary permeability under normal and pathological conditions are discussed, and there is a detailed account of the lymph flow from the various parts of the body It seems that much is known about the lymph flow from some organs and regions of the body and hardly anything about the flow from others Much work on lymph flow has been done in Professor Drinker's own laboratory

Experiments have resulted in lymph being obtained from several of the less accessible parts of the body In connective tissues the lymphatics seem to be relatively permeable, particles and proteins entering them with ease and rapidity From mucous and serous surfaces, fluids and the smaller protein molecules readily enter the lymphatics, whereas the larger proteins and particles as a rule do so only very slowly Absorption from the nasal cavity has been studied in great detail, and an account is given of the passage of virulent bacteria and viruses from the nasal mucosa into the cervical lymph The authors think it almost certain that substances will only pass through the cribriform plate from within outwards They believe that the lymph, and in particular the lymphocytes, may play an important part in the dissemination of viruses throughout the body Although the vaccinia virus, which is pathogenic for rabbits, can be isolated from the cervical lymphatics soon after instillation into the animal's nose, it is apparently impossible to detect the virus of poliomyelitis in the lymph after it has been dropped into the nasal cavities of monkeys

Factors controlling the flow of lymph are discussed at length In the limbs, at any rate, the flow is more or less independent of the production of lymph, the formation of lymph depends on capillary permeability, but the removal from the tissues of the fluid so extruded depends almost entirely on extrinsic factors such as movement, massage and posture The authors maintain that lymph and tissue fluid are identical, but it is not clear how much of the fluid actually exists free among the tissues

The second part of the book reviews the many theories which have been brought forward to explain the functions of lymphocytes and lymphoid tissue The mystery remains complete, but the summary of a very extensive literature is an able one It is interesting to learn that phylogenetically the lymphoid tissue has quite a separate origin from the lymphatic vessels The authors go to some lengths to emphasise their belief that the l play a very small part in the reduction of œdema limbs It is difficult to agree with them since, as point out, it has been clearly shown that the lym in œdematous areas are held widely open, thus flow of lymph along them would be greatly ai by movements and pressure so slight as to produce increase of flow in a normal limb Again, the rea not left with a clear idea of the view the authors about the part played by the lymphatics in the fight against infection

Sick Children

(4th ed) DONALD PATERSON, M D Edin, F R C P London Cassell and Co Pp 610 15*s*

THIS is one of the smaller handbooks of children diseases, but it is unusually comprehensive To tak two examples, mental tests suitable for various age are printed in an appendix, and there is a set of radio grams showing the ossification of the wrist and hand from birth to the age of fifteen The index is fairly good and the illustrations are excellent A number of items are frankly abstracts, references to the originals being faithfully given, and the effect of authenticity thus produced is maintained by the practical tone of the whole book

Textbook of the Practice of Medicine

(6th ed) Editor FREDERICK W PRICE, M D Edin, F R C P London Humphrey Milford, Oxford University Press Pp 2032 38*s*

AFTER many war-time vicissitudes the new edition of this well-established textbook has at last appeared Revision, though widespread and on the whole adequate has been mainly in detail, such innovations as the sulphonamide group, the newer insulins, chest-leads in electrocardiography, and rupture of the intervertebral disc have been introduced The two war years which have elapsed since the last edition appeared have witnessed comparatively few advances in medicine, but it is somewhat surprising to find no reference to the medical aspects of poison gases or of shock, and a section on military medicine would not have been out of place More space is allotted to visceroptosis than to either carcinoma of the stomach or jaundice and the Meulengracht diet is dismissed in a few scathing words The section on diabetes mellitus is more likely to confuse than enlighten the reader, and perhaps the editor should have made it clearer that his own views on primary cardiac strain are unorthodox Of the 99 illustrations all but 22 (of which at least 2 could have been spared) fall in one section These are minor criticisms and the new edition is well representative of the teaching of the London medical schools

Second Yearbook of Research and Statistical Methodology

Editor O K BUROS New Jersey The Gryphon Press Pp 383 $5

IN this second venture, which in minor ways is a great improvement on the first, the editor lists 390 books, written in English and published since 1933, which deal with statistical methods, scientific method, social relations of science and similar subject together with selections from the published reviews of them Any such list is clearly helpful to the research worker, the teacher and the taught, but the value of "evaluative comments" contained in reviews is open to some doubt, reviews of the same book being often laudatory, derogatory or vacuous according to the school of the reviewer Many reviews deserve no further publicity than they originally received, though Mr Buros rather optimistically hopes that his reproduction of them will stimulate editors and reviewers to do better Given sufficient help and money he would like to extend his field to books in other languages and to non critical and critical abstracts of the literature on research and statistical methodology This might be of greater benefit to interested workers than the present pages of extracts from many reviews of the same book Incidentally, the index of names leaves much to be desired, the page reference being to the book listed Mr A, therefore, is mentioned in connexion with book no 20, but since references to book no 20 occupy 11½ pages it takes Mr A some time to learn what is said of him or what he said of it rting with 13–27 mg per 100 g has this amount luced to 1 or 2 mg—a worthless amount Kale ffers a reduction from 155 mg to 7, this making it most useless as a source of vitamin C, though still luable for vitamin A and probably for calcium and on There can be little doubt that similar facts ould be discovered with other sources of vitamin C ich as swedes, turnips and spinach

None the less, the hay-box used with discretion is an xtremely valuable addition to cooking appliances ven in peace-time and may be invaluable in war-ime It will cook most vegetables, stews, meats for oiling, and most cereals and milk puddings, though it s not very successful with rice And foods left to ook in it are usually hot even after a lapse of 6 hours lepending on the efficiency of the heat insulation and he initial volume of the food The discretion necessary can be taught and learnt unfortunately only by hose with a modicum of dietetics and a knowledge of where to turn for information It is a gross pity that there is a dearth of trained dietitians to educate the public in hay-box and other cookery, and that, though the need has been outspoken for the last decade and more especially since the war began, little or nothing has been done by any ministry or public educational body to supply such teachers

IMMUNITY TO TETANUS

Tetanus is, like gas gangrene, a rare infection in civil practice, both need the opportunity of wounds peculiar to warfare if they are to flourish The deep penetrating wound soiled by infected earth or clothing and left unattended for twenty-four hours or more provides the ideal conditions for the anaerobic growth of *Clostridium tetani*, and it was only when such wounds were surgically excised and the patient given prophylactic tetanus antitoxin that the incidence of tetanus in the 1914–18 war was reduced from 8–9 per 1000 to less than 1 per 1000 Since then, active immunisation with tetanus toxoid has passed from the experimental stage and the protection of army horses against lockjaw to its clinical application for the protection of the armed forces Boyd[1] showed that immunity to tetanus, taking 0 01 unit of antitoxin per c cm as the effective lower limit could best be obtained by giving two injections each of 1 c cm of tetanus toxoid at an interval of not less than six weeks The injections produce little or no upset, the only undesirable complication is the rare occurrence of an anaphylactoid reaction after the second dose, apparently due to a protein derivative in the culture-medium,[2] and readily countered by an injection of adrenaline That this risk is very rare is borne out by the absence of systemic reaction noted by Peshkin[3] in the immunisation with alum-precipitated diphtheria and tetanus toxoid of 186 allergic children

The efficacy of Boyd s method of immunisation was largely substantiated by the absence of tetanus among the 80% or so of the B E F in France who were actively immunised for circumstances prevented a large proportion of the wounded from getting in addition the recommended dose of tetanus antitoxin[4], yet cases of tetanus were reported only among those who were not actively immunised Confirmation of Boyd s preliminary work has lately come from two sources in this country Marvell and Parish[5] who recommended intramuscular rather than subcutaneous injection, found that in 116 persons given two 1 c cm doses of tetanus toxoid at an average interval of six weeks the titre was less than 0 01 unit per c cm in only 13 out of 187 blood-samples tested at intervals ranging from one to nine months after the second injection, 11 of these 13 samples were examined six to nine months after the second dose It was noted that women responded better to immunisation than men, whereas staff (stablemen and technicians in the tetanus laboratory) whose work might bring them into contact with tetanus toxin gave no better response than other male staff Those with low titres after the second dose were given a third "boosting" dose which was most effective in raising the titre if given after a long interval (seven to nine months), Peshkin noted the same phenomenon among his immunised children These findings have been substantially corroborated by Evans On another page he records an investigation of blood-samples from staff of the National Institute for Medical Research who were given two doses of tetanus toxoid at an interval of nine weeks While none of 81 subjects had 0 01 unit of antitoxin per c cm before the first injection nine weeks later a fifth of them developed more than 0 1 unit in response to the first dose, which suggests that some of them already had a low basal immunity The second injection brought every person above the 0 01 threshold, and the level of immunity noted seventeen weeks after this dose was largely maintained ten months later, Marvell and Parish, and Peshkin, on the other hand noted a waning immunity in a proportion of cases with the lapse of time Like them, Evans found that a third dose given after an interval of ten months produced a striking rise in titre Thus, the ' injection de rappel of the French given a year or so after primary immunisation, has much to recommend it, for it boosts up an already existing immunity and gives the necessary additional stimulus to those few people who do not respond to the first injections An alternative and apparently effective, method of immunisation against tetanus is that recommended by Ramon and lately supported by MacLean and Holt[6]—the combination of tetanus toxoid with T A B vaccine in two doses given at a month's interval With this combination the immediate antibody response to the tetanus toxoid was much greater than when toxoid was used alone, but the subjects were not followed up to find if the immunity was maintained Another point which is still at issue is whether it is better to give a wounded and immunised man a further injection of toxoid as French and American authorities advise or a dose of tetanus antitoxin as is the recommendation of our Army Medical Service It is conceivable that in a shocked and unattended soldier infected with *Cl tetani* the sudden liberation into the circulation of toxin accumulated at the site of injury might do irreparable damage before the host's protective mechanism could be stimulated to produce antibody in such cases artificial antibody seems desirable Where infection occurs in a healthy non-shocked person, the toxin produced in situ should provide the necessary stimulus without artificial aid from outside burns immobilisation in plaster is being used to keep the healing tissues at rest, and in the deep burn it also enables a barrier of granulations to develop which seals off important structures such as tendons and joints

In the early stage of acute sepsis, except when there is lymphangitis, the use of closed plaster to secure the essential strict immobilisation does not seem desirable In the closed progressive acute lesion, where pus has still to be evacuated, the closed plaster will increase the tension in the tissues walling the forming abscess and is thus to be avoided The time for plaster only begins when effective drainage has been established The experimental work of TRUETA and BARNES shows that only in the draining, inflammatory limb will plaster cause the lymph flow to cease In the early stage of acute sepsis, therefore, strict immobilisation of the joints above and below by splintage, either by plaster slab or other material, is called for As soon as drainage is established the closed-plaster method can be applied As in wounds of war the closed-plaster method is for the open draining wound FRASER[5] has used this method in the treatment of acute osteitis, where after drilling the bone, as advocated by STARR he packed the wound and encased it in plaster DODD[6] insists on strict immobilisation in the treatment of multiple boils He thinks that any movement —squeezing, bathing or fomenting—may detach infected thrombi which may settle in the skin, or may form abscesses in the kidney, ischiorectal fossa or bone He therefore confines the patient to bed, securing rest by infrequent dressings, and by splinting (even for boils of the neck, where he uses a long back splint with foot piece for the head) and his results have been gratifying He also[7] advocates complete rest in the management of abdominal distension after operations on the gut, and most surgeons would agree that immobilisation is the principle to be followed in all forms of intra-abdominal inflammation, though they might differ as to the method by which rest is best secured—for instance, when and in what dosage should morphia be given? In the treatment of infected fingers there has also been difference of opinion about the value of immobilisation As JEAN PIERRE DAVID of Rouen wrote in 1779 "there is a time for rest and a time for motion in the treatment of most surgical conditions" Those who use plaster for wounded fingers hold that complete rest for two or three weeks does not lead to stiffness, and longer periods are harmless if the position of the fingers is changed once a fortnight When the inflammation has subsided, they say, and there is no risk of tearing capillaries or spreading infection, movement should begin

Nevertheless in all these cases the disadvantages of immobilisation, especially if long continued, must be recognised, the inconvenience of the patient must be considered and a balanced outlook maintained The theoretical foundations of the principle of complete rest have been established, and in this war its application to infected wounds has been brilliantly successful, it still remains to extend its use and define its indications for the treatment of other infections.

THE HAY-BOX REDIVIVUS

SINCE the beginning of this century the has enjoyed a deserved reputation among conn of cookery, and also among lazy amateur cooks prefer other activities to standing over the stove It is well known that cooking is possible the boiling point of water Indeed it is doubtful if interior of a roast joint ever reaches such a te ture The juiciness, palatability and digestibility the inner cuts are largely due to this fact high-class restaurants use the plan of raising temperature of the outside of their joints to a point for a short time in the oven and then them to a place where the temperature is lower, that cooking may continue slowly for a sid time This not only produces a more tender cut is economical in that not so much of the juices of meat are lost to the exterior Cooking is much slower by these means, but much less attention is needed after the initial stage, and where time is of little consideration slowness is no disadvantage A similar principle underlies the cooking of food in a hay box. Food is brought to the boiling point and then after a few minutes' exposure to that temperature is transferred in its container to a heat-insulated box and left for hours to cook in its residual heat For many years there have been on the market "fireless cookers which work on this principle Foods are boiled in highly polished saucepans, which, when their contents are hot throughout, are removed, tightly sealed, to a metal-lined container into which the saucepans fit snugly This container is insulated from heat loss by a packing of kapok, asbestos or some other non conductor of heat Some hours later, when the container is opened, the food is found to be admirably cooked and may still be smoking hot and ready to serve An amateur apparatus can easily be constructed from a packing case with hay as the non-conductor, using a weighted cushion also stuffed tightly with hay as a lid Hence comes the term "hay-box cookery" for all such methods of preparing food for the table

Hay-box cookery comes to the fore in war-time It saves fuel It needs little attention It releases a person for other duties When, as at present, married women are at work on munitions, it may solve the problem of the hot meal on the return home at the end of the shift Also foods can be cooked overnight so that little preparation is needed in the morning before an early start for the works Earnest amateurs therefore rush in to instruct the working-classes in hay-box cookery, and this naturally arouses the inhibitory instinct of other earnest amateurs who a "What about killing (sic) the vitamins?" The hay box has sundry disadvantages The home made apparatus is not easy to make or to keep sweet and there is a considerable destruction of vitamin C varying with the length of time the foods remain in the box Experiments on brussels sprouts, kale and potatoes show a diminution which in the two last named is really serious Brussels sprouts, with 123 mg per 100 g in the raw state have this reduced to 66 after boiling for 15 minutes Two hours cooking in the box, after this, reduces the amount to 29 and six hours to 24 The sprouts have thus lost two thirds of their original content, though even so they are still a valuable source of vitamin C The potato, other occupation without training Information about ir capacity, obtained from the hospital, will be passed their local employment exchanges and they will be vited to seek help there if they find difficulty in getting nployment

The Ministry recognises how important it is for the man achieve the fullest possible physical restoration both uring the time he is in hospital and when he begins ork, and that if he is to keep his job when peace turns he must be fitted to do not any job passably ut one particular job better than most, and it must be job which will still exist in peace-time It may well e true, as the Minister of Labour says, that 75% of isabled people are fit to take up some kind of work gain, and that they could master many of the processes now being taught at Government training centres and echnical colleges The scheme puts such training in the orefront Since it will not be easy in such centres to give curative as well as technical training, courses are also to be provided at institutions which already have special experience of preparing the disabled for industry In addition it is hoped that some employers will agree to provide training for disabled men But there is some evidence that people who have qualified at Government training centres are not always being used, at present, on the work for which they have been trained It would need much closer supervision of the factories than is now customary to ensure that the disabled employees are never given work detrimental to their condition If a return to work produces a loss instead of an advance in power and function, it will be a disaster to the injured person instead of a benefit All this applies with special force to patients boarded out of the Army, many of whom at present flit uneasily from unsuitable job to unsuitable job before finding one within their compass, or too often lapse into the ranks of the unemployable Possibly, too, the official attitude to the question of reabsorption into industry has been too narrow, harping too much on surgical conditions, which though they cover most of the air raid casualties represent only some 20% of the conditions compelling discharge of men from the Army Medical conditions are probably responsible for almost as many incapacities among the civil population as among soldiers Nicoll[3] has discussed the rehabilitation of the injured with reference to the coal mining industry, and much of what he says holds for a range of disabilities stretching far beyond the results of injury

Mr Bevin plans that training allowances of 42*s* a week shall be paid to men, 33*s* to women, 17*s* to boys and 15*s* to girls This wide discrimination between the rates to the sexes seems scarcely necessary, since dependants' allowances are to be paid to those in training at the rate of 7*s* 6*d* for a wife and 3*s* for each child The principle of Mr Bevin's plan, however, is so good that we must hope to see it put speedily into force, minor defects can be put right once it is working

OPERATION FOR HYPERTENSION

THE experimental finding that in animals renal ischæmia will produce persistent hypertension has clinical implications which are now being explored At a combined meeting of the sections of medicine and of therapeutics and pharmacology of the Royal Society of Medicine on Nov 11, Prof G W Pickering gave it as his opinion that experimental results will in due course explain most of the human cases of hypertension Dr Clifford Wilson had produced renal lesions in rats by partially occluding one of the renal arteries, pathological changes were found only in the kidney with an intact circulation and were completely absent in the clamped kidney, they consisted of fibrinoid arteriolar necrosis and endarteritis with occasional involvement of the glomeruli, and closely resembled those in sections from human cases of malignant hypertension He suggests that the histological changes found in the kidney in the terminal stages of Bright's disease are produced by hypertension Since the lesions in experimental animals only affect the unclamped kidney the most obvious explanation seems to be that they are caused by the hypertension, and this suggests a vicious circle renal ischæmia leading to hypertension which in turn produces renal vascular lesions with increased renal ischæmia, and so on

In the last year or so there have been a number of reports of hypertension associated with non-nephritic kidney disease, and in cases where the lesion was unilateral removal of the affected kidney has given encouraging results Dr Robert Platt, at the same meeting described such a case in a girl of 8 who had a blood-pressure of 220/120 mm Hg and bilateral papillœdema and retinitis A year before, investigation for *Bacillus coli* infection had shown a functionless left kidney The prognosis at the time of the second examination was so grave that the affected kidney was removed and proved to be small and hypoplastic The day after operation the blood-pressure fell to 155/95 mm Hg and five months later was only 125/70 The child has remained well and has now no swelling of the discs or retinal œdema Similar cases of unilateral nephrectomy were summarised recently in our columns by Richardson and Smart,[1] who added 2 cases of their own to those recorded One of these was a case of tuberculosis of the kidney and the other of hypernephroma, in both, removal of the damaged kidney caused a dramatic fall in blood-pressure maintained for several months, up to the time of publication Barker and Walters[2] have reported successful results of operation in 5 cases of unilateral pyelonephritis All the reported cases are readily explained by analogy with experimental results, they are generally associated with occlusion of the renal artery or vein, diminished urinary outflow, or disease of the kidney substance

The biochemical aspects are being investigated by several groups of workers, intent on isolating the active substances produced by the damaged kidney and causing the rise of blood pressure Their findings up to the present were reviewed in our issue of Nov 8 (p 575) In the meantime it is evident that the renal function must be investigated in all cases of hypertension Presumably many cases of hypertension with unilateral renal dysfunction might be saved by operation, provided removal of the damaged kidney was carried out before vascular changes have been produced in the contralateral kidney An example of such a case is to be found in the report by Davson[3] of an autopsy in which one kidney showed a hydatid cyst and the other the typical histology of malignant hypertension, presumably secondary to the partial occlusion of the renal vessels of the opposite side by the growth of the cyst

It remains to be seen what proportion of cases of hypertension are due to renal ischæmia No certain correlation has been shown between non-nephritic kidney disease and hypertension, but Goldblatt's experiments do not suggest that the renal damage necessary to cause hypertension need be gross, in fact as a rule renal function is normal in his animals during experiments Slight degrees of blockage in the renal arteries of man cannot necessarily be demonstrated during life by methods so far evolved, and at present the only certain way of proving that hypertension is not associated with such minor degrees of occlusion is to wait for the autopsy report A series of such reports has been recorded by Blackman[4] who investigated the renal arteries of 50 cases of so-called essential hypertension and found the

A MINISTRY OF MEDICAL SERVICES

THE demand for a reorganisation of our medical and health services grows increasingly vocal, the latest exposition being contained in a booklet[1] published by the British Association for Labour Legislation, and written by Dame Janet Campbell and Dr H M Vernon, both of whom have long experience of public administration as well as of clinical work Written mainly for the lay public, the greater part of the book is occupied by a summary of the recognised merits and defects of the health services as they exist and function at present—facts with which most medical readers are now familiar The authors agree that the main object to be borne in mind in reconstructing our medical services is to secure, for every man, woman and child in proportion to their several needs, all the medical skill, knowledge and institutional amenities available, independently of individual ability to pay for them As to method, Dame Janet Campbell apparently favours a great extension and expansion of the panel service first because it is a system in being, and secondly because it goes a long way towards satisfying the democratic case for freedom of choice She would also make it include necessary consultant, specialist and hospital services The approved societies would cease to have any connexion with the medical services, beyond accepting the doctor's certificate of sickness and incapacity—though, as a matter of fact, apart from what are now called extra benefits, there is little other connexion at the present time But the novel suggestion of the booklet is that the medical and nursing services should be altogether dissociated from the Ministry of Health, a new "Ministry of Medical and Nursing and Social Services" being set up to organise post-war medical reconstruction It may well be doubted, however, if it would be wise from a national point of view, or in the long run from the narrower point of view of the profession, to dissociate doctoring and nursing from other organised state activities which, we are coming to realise, have a direct bearing on national and personal health

SURGERY FOR SYRINGOMYELIA

WHEN the nature of a disease is imperfectly known the response to various forms of treatment carried out more or less empirically must be the principal guide to its management For this reason the paper in which Worster-Drought, Wakeley and Shafar[2] record their experience of surgical treatment in ten cases of syringomyelia is of considerable importance There are two good reasons for operation when cavitation causes distension of the cord so gross as to block the subarachnoid space One is that the pressure on the long tracts in the cord can be most effectively relieved by draining the cavity, the other is the possibility that the signs and symptoms may be due not to a syringomyelic cavity but to an intramedullary tumour It must be recognised, however, that cavitation rarely progresses to this extent —in the present series, for example, only one out of the ten cases showed signs of a subarachnoid block, though it may be added that, as one might expect, considerable improvement followed operation in this case Three other patients, however, derived similar benefit from the opening up of cavities which had neither obstructed the subarachnoid space nor produced symptoms in the legs, though changes in the reflexes did indicate some interference with the long tracts Under such circumstances the permanent clinical manifestations must be due to local destruction of the cord, while the signs which up after the cavity has been drained may be a to œdema and vascular changes in its im neighbourhood These changes seem to be the pressure within the cavity, which Worster D and his colleagues consider the most important influencing the response to surgical treatment pressure does not necessarily vary directly with the of the cavity, but should it be low little can be from operation, since signs and symptoms then entirely on destruction of nervous tissue and glial growth, neither of which can be affected by myelo Unfortunately it is not possible to distinguish between the two pathological varieties of syringomyelia —the "dry" form in which gliosis predominates and surgery is useless, and the "wet" in which cavitation is the chief feature and removal of the fluid may be beneficial In addition to draining a cavity an attempt may be made to prevent its refilling either by making the drainage opening a permanent one or by obliterating the cavity The former may be achieved by fixing silver clips to the edges of the opening, by placing muscle tissue between them, or by suturing the lining membrane to the arachnoid on each side In the present series the walls of the cavity, which had fallen into apposition after escape of the fluid, were painted with tincture of iodine in the hope that the resultant inflammatory reaction might lead to their permanent adhesion with obliteration of the cavity It is to be hoped that other surgeons will record their experience so that some estimate may be formed of the proportion of cases of syringomyelia which may be expected to benefit from operation Unfortunately it will not be possible to foretell the result in any individual case until the distinction between gliosis and cavitation can be made on clinical grounds with a greater degree of accuracy than is now possible

MAN-POWER OF THE DISABLED

AN injury which disables a man for the occupation he has been following does not necessarily incapacitate him for other useful work The Minister of Labour has prepared a plan[1] for training people disabled while on war service or in civil life and for settling them again in industry. He believes that large numbers of disabled men and women could hold good jobs on their merits and not simply because of considerate treatment For the time being preference in training may be given to war service or air raid victims, but the scheme will form the basis for a post-war resettlement scheme covering all persons over 16 disabled in road, industrial or factory accidents The value of rehabilitation is not only that it fits a man to earn his living but that properly used it can restore power to damaged muscles and joints and thus reduce disability This was proved during the last war, and remains a principle at Enham Village Settlement, it was recently illustrated by the report in our columns[2] on 40 cases treated at the Allendale Curative Workshops The Minister of Health is favouring hospital schemes for the rehabilitation of injured people, and Mr Ernest Bevin's plan is designed to work in with these scheme The patient will be interviewed by a representative of the Ministry of Labour while he is still in hospital and the choice of suitable training for him will depend on his own preference, on the nature of his disablement and on the opportunity and demand in particular trades By conferring with the physicians and surgeons in charge of the case it should be possible to arrange work within the patient's capacity, and such early contact with him should enable the ministry to plan ahead and ensure that a job is available when he is ready to take it No doubt many patients will be able to resume their former or

INJURIES AND DISEASES OF WAR

A NATIONAL PATHOLOGICAL COLLECTION

So far no steps have been taken to replace the ecimens illustrating injuries and diseases of war which as made between 1914 and 1918 and housed at e Royal College of Surgeons. These were mostly deroyed in the air-raid of May 10–11 although, as noted the college annual report, Tonks's famous pictures the facial injuries of the last war are intact. The ollege and the War Office have asked the Medical esearch Council to make a new collection and a subommittee of the War Wounds Committee has been ppointed to consider how this might be done. The hree fighting Services, the Ministry of Health, the epartment of Health for Scotland, the Royal College f Physicians of London and the Royal College of urgeons of England are represented on the subcommittee, and they hope that the whole profession will help n the task of collecting material. This should include pecimens, pictures, photographs and radiograms illustrating lesions produced by missiles, war gases, explosion gases, secondary missiles (such as fragments of masonry or debris), crush injuries, the effects of blast in air or water, and burns from any causes; there should also be material illustrating repair, infection and the results of treatment.

PRELIMINARY CARE OF SPECIMENS

The value of pathological specimens when mounted depends on discriminating choice of material, the care taken in collection and the preliminary treatment. The subcommittee offers the following advice.

Only those specimens should be chosen in which the lesions can be clearly displayed.

The collector should take every care to maintain the shape and form of the specimen during fixation, when the greatest amount of shrinkage and distortion is liable to take place. A hollow viscus or any tubular structure should be suitably packed with absorbent cotton-wool soaked in formol saline, before the specimen is immersed in the fixative. Structures such as nerves, arteries, segments of bowel or slices of solid organs should be fixed in position on a suitable frame, to prevent shrinkage, bending and distortion.

Fixation should be carried out in a convenient receptable such as a bucket (only if enamelled or tinned), a basin or a jar; the volume of the receptacle should be at least twice and preferably three times that of the specimen. This ensures that the greater part of the weight of the specimen is supported by the fluid, but cotton-wool should be placed at the bottom of the receptacle to prevent flattening. Bottles with relatively narrow necks, through which specimens would need to be forced, should be avoided. The receptacle should be covered with a lid, but need not necessarily be tightly corked.

The fixative used should be 4% formol saline. Stronger solutions do not give better fixation and tend to inhibit penetration of the tissues. In the case of solid organs, with the exception of the brain, the fixative never penetrates more than about ¼ in. For this reason all dissection and trimming should be carried out before fixation is completed.

The fixative is made up of: sodium chloride 9 g., commercial formalin (40% formaldehyde) 100 c.cm., water 1000 c.cm. Formalin solutions tend to become acid by oxidation to formic acid, and it is important that any acid formed should be neutralised. This can be done by adding a small quantity of carbonate of magnesia (mag. carb. pond.), chalk or marble chips to the stock solution, which should be stirred occasionally. The clear neutralised fluid for fixation can then be decanted as required.

The specimen should remain in the fixative until it is sufficiently hardened for safe dispatch by post to the receiving depot, where fixation will be completed if necessary. The time required varies considerably with the nature of the specimen. Small delicate specimens will be adequately fixed in a few hours, whereas larger, fatty specimens may require a week for fixation. Since glycerin and other mounting fluids are now almost unobtainable, no large scale attempt will be made at present to restore the colour of specimens. The specimens will be stored in separate containers to prevent crushing and distortion, and they will be mounted when supplies of mounting fluids are available.

For dispatch by post, a specimen should be taken out of the fixative, drained of excess fluid, wrapped in lint moistened in fixative, and covered with jaconet. The parcel should then be packed in dry wood wool or sawdust, in a suitable box. The dry packing should be sufficient to prevent leakage during transit, and the box should be clearly labelled "Pathological Specimen." A precise history should be sent with each specimen, giving the cause of the injury, treatment and clinical progress, and emphasising any pathological point that the collector regarded as important. The name and age of the casualty, the hospital concerned, and the name of the collector should be stated. The history may be sent by separate post, or in the box with the specimen, provided that the papers are protected from damage by moisture. An acknowledgment, with comments on the condition of the specimen on arrival, will be sent to the collector.

Specimens are to be sent in the first place to one of two receiving depots where they can be temporarily classified and stored. For Scotland and the north the depot is the pathological department of the University of Leeds, and specimens should be addressed to Prof. M. J. Stewart. The depot for the south is at Hill End Hospital, St. Albans, Herts, and specimens should be addressed to Prof. Geoffrey Hadfield.

MEDICAL WAR RELIEF FUND

SINCE this fund was set up just over a year ago over £34,000 has been contributed by the medical profession at home and overseas to provide immediate help for British doctors and their families to whom the war has brought financial hardship. The need is sometimes temporary but it is almost always urgent, and within a few weeks of the fund's beginning the distribution committee had made its first awards, and during its first year 44 applicants have been helped with a total call on the fund of nearly £5000. They include the dependants of 5 doctors killed on active service, 16 doctors whose homes or consulting-rooms have been damaged by bombing, 7 who have lost their practices as a result of evacuation, 8 whose incomes dropped when they joined the services or who needed help to set up in practice again after resigning their commissions because of ill health. An award was also made to the wife of a doctor who has remained in one of the Channel Islands after the German occupation. The following three cases illustrate the scope of the work.

Dr. G., a senior general practitioner, lost his life in a raid in which his house was completely destroyed. His only child was killed at the same time. The widow lost her clothing and other possessions and although the doctor's estate would eventually furnish her with a modest income she was temporarily without means. She was awarded a suitable sum as a gift to provide for her immediate needs.

Dr. M., a specialist serving in the R.A.M.C., was killed on active service, leaving a widow and child. Mrs. M. has been awarded a gift (to be administered by the Royal Medical Benevolent Fund) which will supplement her small income during the child's remaining years at school. As Dr. M.'s elderly mother had been partially dependent on him a similar arrangement has been made in her case, and Mrs. M. senior has been introduced to two other benevolent societies one of which has awarded her a small grant while the other has given more permanent assistance in the form of a small pension.

Dr. K. is an elderly consultant. His consulting rooms were bombed and destroyed with the furniture, instruments and books which they contained. The income from his practice had diminished owing to the war and although he had no debts of any magnitude neither had he the means to acquire new premises and equipment while awaiting the payment of war-damage compensation. He was awarded a substantial sum for this purpose—the greater part as a loan and the remainder as a gift.

These cases show grants to widows and dependants which have been made as gifts, but where the applicant was a doctor whose troubles seemed to be temporary part of the help was given as a loan and some of these are already being repaid. The gifts amounted to £4795 and the loans to £3040. The distribution subcommittee of the fund has worked in close cooperation with the Royal Medical Benevolent Fund and acknowledges its debt to the accumulated wisdom and experience of that body. Not only has the R.M.B.F. provided applicants with persuasive introductions to other funds which have granted supplementary awards, but it has undertaken the administration of long-term educational grants, an arrangement which will assure widows with young children of continued counsel and help when the work of the war fund is happily accomplished.

The generosity of the B.M.A. and R.M.B.F. has made it possible to keep the administrative costs of the fund for the year down to £150, or less than 0.5% of the amount extraordinarily high proportion of 86% with some degree of stenosis He also found that clinical and histological evidence of vascular nephritis was present in only 56% of cases In all 50 he found arteriosclerotic plaques in the intrarenal arteries It is noteworthy that Goormaghtigh claims[5] to have demonstrated endocrine cells, similar to the chromophil cells of the anterior pituitary, in the walls of the renal arterioles of animals and he states that during clamping of the renal artery these cells become hyperplastic If his findings are confirmed pathologists may be able to demonstrate similar cells in human kidneys from cases of hypertension

RENAL COMPLICATIONS OF CHEMOTHERAPY

HÆMATURIA is now established as an important complication of treatment with sulphapyridine and the more recent chemotherapeutic drugs The clinical picture produced has been described by Laird[6] in three stages In the first stage, hæmaturia is microscopic only and pain is sometimes present, in the second, the hæmaturia is gross and usually accompanied by pain, but clears up rapidly on withdrawing the drug and giving ample fluids, and, in the third, despite such remedial measures, there is impairment of renal function which may lead to nitrogen retention, anuria and death Treatment is straightforward, withdrawal of the drug and the pushing of fluids producing rapid improvement in cases in the first and second stages Where it is impossible to administer abundant fluids by mouth because of vomiting or unconsciousness, 4 28% sodium sulphate with 10% glucose in normal saline should be given by the intravenous drip method In the third stage, with anuria, ureteric catheterisation has proved a life saving measure Hæmaturia due to chemotherapy should be diagnosed in the earlier stages in which the simple measures are uniformly successful It results from the deposition of crystals of the acetylated compounds in the renal tract, and Lehr and Antopol,[7] investigating the influence of urine on the crystal shape of acetylated sulphanilamide compounds, observed that the characteristic urinary crystals were not formed in highly dilute urines (sp gr 1014 or less) Macroscopic hæmaturia is thus most likely to develop in patients in whom the daily urinary output is allowed to fall below 1500 c cm It can be prevented by maintaining the daily fluid intake above 3000 c cm, and it would be regrettable if the importance of this simple preventive measure became minimised by reports on the effects of the concurrent administration of alkali Sunderman and Pepper[8] and Climenko and Barlow[9] have determined that acetylsulphathiazole is more soluble in alkaline than in acid urine, while Schwartz and others[10] have demonstrated a greater number and incidence of crystals of the drug in the urines of 50 pneumonia cases treated with sulphathiazole than in 50 comparable cases receiving the same drug in similar dosage but in which the concurrent use of sodium bicarbonate had rendered the urine less acid In this investigation the urine was tested with litmus only and those giving a neutral reaction were included with those classed as alkaline, in addition, no record is given of fluid intake or the specific gravity of the urine specimens The validity of the conclusions must be viewed with reserve until the work is repeated under more carefully controlled conditions Furthermore, Loewenberg and his colleagues[11] have described a case of pneumonia, treated with equal amounts of thiazole and sodium citrate, in which acetylsulphathiazole were found, although the was alkaline Similarly with sulphapyridine evidence that the administration of alkali will not itself prevent renal complications and that sulphapyridine may crystallise out in alkaline Haviland and Bratton, in a personal Sadusk and his colleagues have stated that the of acetylsulphapyridine in urine remains essentiall same for a range of pH 3 3–7 4 and that its solubili pH 7 9 is not significantly greater

Alkalisation of the urine, then, cannot be counted to prevent renal complications during chemo and any benefit that does result from alkalis is prob due to the diuresis they produce But the requirement for adequate diuresis is an adequate flui intake We can take the patient to the water easily enough, but there is the familiar difficulty in making him drink He must have the reason for the procession glasses of water explained to him, and something can be gained by presenting the fluid in more attractive form, though even this is difficult now that citrous fruits are scarce When the patient is vomiting other routes must supplement fluids by mouth Much ingenuity will in fact be required on the part of the attendants if the necessary five pints a day are to go in, but if they are taken and retained we can be as sure as anything is in medicine that there will be no crystallisation of the drug in the renal tract

RADIOGRAPHY OF THE HEART

IN the examination of the heart radiography is still widely regarded as a poor second to electrocardiography This is partly because the latter method is older and the necessary apparatus more compact A more substantial reason however is that the information given by the electrocardiogram is usually clear cut whereas the shape and size of the heart are subject to wide normal variation according to body-weight, shape of the thorax and movements of respiration, which must be discounted before any deductions are drawn The value of radiology has recently been emphasised by Denstad,[13] whose work brings into prominence the pathological conditions which, hidden to clinical and electrocardiographic examination, can be revealed by radiology Although electrocardiographic changes and enlargement often run parallel, considerable enlargement can exist with a normal e c g, while severe changes, such as branch block or inverted T wave, may exist with little if any enlargement From the diagnostic point of view radiography is of great value in mitral disease where the characteristic murmurs may be indefinite In *auricular fibrillation* the heart is alway enlarged, and Denstad believes that fibrillation can only occur after a certain degree of dilatation has been reached In hypertension enlargement is generally commensurate with the severity of the symptoms and i a more reliable index of the prognosis than the blood pressure In this as in degenerative condition radiology is of special worth since the enlargement cannot always be determined clinically In pericarditis radiology gives invaluable information in revealing the size of the heart itself the degree of calcification and fixation and hence the advisability of operation The work of Denstad and others shows that without radiology the examination of the heart cannot be regarded as complete

In England Now

Running Commentary by Peripatetic Correspondents

IF the G P of the future is not to be a martyr to riter's cramp, ambidexterity must be forthwith introiced into the curriculum Certificate-writing has a eat future At present it is only in its infancy and obably does not occupy more than a quarter of the octor's working day I don't think that I am ever lled on to sign more than 35 different kinds of certicate Let's have them all in during one surgery hour s well we may) and tot them up First, then we have , a farmhand with an infected toe That's easy bviously he can't work till his toe is better so I give him weekly panel certificate In totters old B with paralys agitans He gets a pink certificate, so that I don't ave to write another one for him for a whole month h, wait a bit—he belongs to two private clubs which ay him a few shillings and he might as well have them, o I sign them for him Total so far 3 Mrs C brings n her little boy with a cough He is she tells me, on the atural deposit and produces the appropriate form—only iagnosis and initials to be written on that one Her usband has also looked in because he has broken his late, so he gets a certificate stating that he requires ental treatment In comes Miss D, she gets headches, worse after sewing or reading, and she thinks uite rightly, that she needs glasses I give her an phthalmic certificate and call for the next patient It s Mr E, big fat and elderly, to say that his truss is lmost wear'd out and he needs a new one I give him a ertificate for a surgical appliance and mop my brow otal to date 7 Mrs F has sent up her little girl with a ertificate claiming maternity benefit The nurse could ave signed this but Mrs F forgot to ask her when she as attending, so perhaps the doctor will oblige He does h, and Mrs F wants an extra milk certificate for nursing nothers and Auntie who is expecting, wants one too—0 up The wife of a sailor wants a form signed so that he can draw her separation allowance, she is followed y the wife of a soldier and the wife of an airman in imilar circumstances Total, 13 Old Mrs G and her idowed daughter Mrs H come in together Mrs G ants her O A P paper signed and Mrs H one for the idows' pension A J P lawyer, minister of religion r other responsible person could sign these, but the doctor s unfortunately so much more accessible than other esponsible persons Hello here comes young I the elegraph boy, with an almost invisible dog-bite There s a regular questionnaire to fill in about this, but it is one at last and I makes way for his father, a postman, with lumbago He can't work with lumbago poor chap, so I give him a post-office certificate 17 Mrs J's husband is a diabetic so needs a certificate for the food office, and could she have a certificate so that she may get glucose for the baby? You know how he needs glucose, doctor And you said little Charlie wasn't to go back to school till his throat was quite better—well, he school attendance officer keeps badgering her, so ould she have a note to show him No I dig in my oes If the school attendance officer won't take her word for it that little Charlie is under the doctor, let him ome and see me That settles the school attendance fficer and gets me out of writing one more certificate Ir K is still far from right in his stomach in spite of he operation which I said would cure it I didn't, but gree that he should have extra milk and write a certiicate accordingly—20 up Miss L is a nice, bright girl nd won't keep me a minute Just sign this to say that he is fit for work in the NAAFI I examine her, nswer the questions and sign Mr M is going to work n the dockyard and has a special form for me to fill in nd sign—I examine him and do so At this point the elieving officer creates a diversion by looking in to say hat old Miss N who was always a little odd, has identiied herself with Hitler, and, in a state of nature, is arranguing the delighted multitude from an upstairs window I slip out and certify her Back again, I find Ir O in great distress He lost both legs in the last ar, has mitral stenosis and has been called up The nan at the labour exchange agrees that Mr O is probably nfit for national service but must just have a line to that ffect from his doctor Mr P really does not take long He is recovering as quickly as he can from a number of bomb wounds and blast effects, but has to have a weekly certificate of unfitness to work It's all a lot of red tape, he says, but I rebuke such levity Mrs Q says that my partner has ordered her daughter to go under the X rays in hospital and she has brought the hospital-aid form for me to sign Mrs R's old father has passed away at last We agree that it's a merciful release for all three of us Even in death he is a nuisance requiring not only a death-certificate but a cremation-certificate as well 28 Only two more patients I see Here's Mr S who has been pulling turnips and got a tenosynovitis, that means an industrial diseases certificate And Mr T has been knocked over by a car He isn't badly hurt but I must fill in a road-accident form Apart from sending off a throat swab, a sputum, a blood for W R a specimen of urine and a request for an X-ray report all of which require certificates that seems to be all Yes I make it 35 kinds When I get home if ever, I can fill in the antenatal examination, emergency midwifery and vaccination forms and write letters to the county council recommending children for T's and A s

* * *

It is not altogether surprising that from time to time the less sensational elements of the lay press look with a tinge of suspicion at successive blasts of semi-official eulogy in praise of this or that source of vitamins It may sometimes appear that the changes are rung a trifle freely on the virtues of many things as they happen to hang heavily on the official hands—sometimes carrots sometimes rose-hips We have recently succumbed to the rose-hip propaganda, and have organised expeditions of our nursing staff into the country lanes in search of berries, "vivid red and slightly soft' to quote the official instructions There is no dearth of volunteers for these outings, despite the fact that the collection of rose hips is known to be prickly, devastating in its effects on stockings and sometimes rather dirty By way of compensation, it involves a not-too-smooth ride a few miles into the countryside, a picnic forenoon and a departure from everyday routine Raiment of ancient vintage is pulled from obscurity, and the party sets out in a gay spirit of adventure, though scarcely perhaps a very fashionable gathering The instructions for picking are explicit enough The fruit is not to be bruised or in any way damaged, and the berries brought back as soon as possible after picking in suitable containers—'baskets, not tins"

Back at the hospital the work of extraction begins The hips are placed in a pan, covered with water and subsequently mashed with a wooden spoon, and the mass squeezed through a jelly bag to obtain the juice, care being taken to filter out the sharp, stiff hairs on account of their reputed capacity to produce gastric irritation Our instructions were that the fruit should be boiled for about a quarter of an hour until tender, which seemed a little odd in view of the known properties of vitamin C and we found when we tested the vitamin content of brew prepared in this way that the prescribed boiling for a quarter of an hour was highly prejudicial to vitamin-C content reducing it to about a third of what it had been at the boiling point On the other hand, nothing short of boiling succeeded in extracting any considerable quantity of vitamin from the fruit, so that we were driven to compromise by slow raising to the boiling point with discontinuance of heating as soon as that was reached We were able in this way to obtain an extract of fairly stable vitamin content though it fell considerably short of the impressive figures issued with the official instructions From the juice we prepared a syrup by the simple addition of sugar and hope piously that the resultant product will keep with us for a period of three months We estimate that it will be necessary to take 3 oz of the syrup daily to produce any appreciable effect

The next problem was to determine how best it could be used In our early enthusiasm we had hoped to carry out something in the nature of a controlled experiment that would enable us to record any improvement in health among the rose-hip takers, but we soon found that an experiment of this sort on any worth-while scale was out of the question, and we had to content ourselves with the selection of a score of nurses who seemed to experience habitually more than their share of the ills of this world These unhappy people were singled out as experimental contributed Economical administration and discerning distribution are necessary for the greater part of the fund's work is believed to lie ahead Contributions may still be sent to the hon secretary at B M A House Tavistock Square London W C 1

OUTPUT AND THE WORKER

"APPLY EXISTING KNOWLEDGE"

THE 21st report of the Select Committee on National Expenditure[1] dealt with labour problems and war output and the Government has now published as the 25th report[2] of the committee a detailed commentary on these recommendations The replies are divided into broad categories such as hours of work, wages, management, discipline industrial relations, transport, food lighting in factories, and incentives to output In the main the Government finds itself in agreement with the views of the committee but differs on some details For instance, it is implied that the committee did not have a clear idea of the functions of the Industrial Health Research Board when it recommended that the board should work in the closest cooperation with, and advise the production departments The responsibility of advising these departments on factory conditions and the health of the workers belongs to the Ministry of Labour—presumably through its Factory Department lately transferred from the Home Office—and the function of the board is to investigate general scientific problems Another recommendation was that the board should carry out investigations to determine the best length of the working week for a wide range of different kinds of work and for men, women, and juveniles, but the board has been doing this kind of work for many years—its first emergency report[3] was a summary of its findings since the last war—and as it has indicated that weekly hours of work should not exceed 60 for men and 55 for women, it appears more useful to apply existing knowledge than to undertake further investigations which would be unlikely to produce different results It is proposed, however, to carry out further inquiries into the conditions of some sections of industry and of particular kinds of work and to ask for the board's help

The recommendation that workpeople should have one day's rest in seven has in the Government's view, been confused with the question of Sunday labour The committee is reminded that they said in their 17th report that the general atmosphere of Sunday is not conducive to the maximal effort, and with the object of maintaining production at its highest level most of the departments concerned agree that Sunday work should be restricted to essential maintenance or repair work and emergencies Some aircraft firms have reported that Sunday work has been given up with beneficial results on output Some workers have resisted the abolition of Sunday work because they receive double pay for that day, and the Government cannot accept the committee's recommendation that the loss of the extra payment for Sundays should be taken into account when fixing wage rates for week-days It seems that 5½ or 6 days a week on production work is the best system which can be arranged and that rota systems are not easy to run because of the additional labour force required and inherent difficulties in organisation and supervision The policy of the Government is, however, that factories should be employed for as much of the 24 hours as possible, and an increasing number are working round the clock

In addition to the committee's recommendations employers have been urged to adapt women's working hours to allow them reasonable time for shopping and in some factories this has been done Discussions have been held with retail trade organisations and with the Ministry of Food and shopkeepers are to be asked to keep their premises open for longer hours on one more day a week and to adjust the shop lunch-hour to suit the industrial workers who may also leave written orders for goods to be collected after closing time

The Government fully endorses the policy that managements should, where possible, take workpeople into their confidence and both groups are encouraged to come together for the exchange of information and · We said recently[4] that if workers are treated like · they will act like them and it is encouraging to see the lesson is being slowly and painfully learnt It agreed that men should be appointed to positions authority in industry, particularly as charge hands foremen, for their qualities of leadership and ability as well as for their technical skill Publicity been given to the established training courses for personnel managers, welfare supervisors, and foremen and also to the work of the conciliation officers of the Ministry of Labour whose main function is to intervene when disputes arise between unorganised sections of industry and employers who do not recognise trade unions It is emphasised that any publicity which created an impression that the services of the conciliation officers were immediately available to settle disputes by direct intervention would tend to undermine the constitutional authority of employers' organisations and trade unions

In reply to a recommendation that a persistent offender who refuses to obey a direction under the Essential Work Order should be dereserved, the Government states that it has always been made clear that men are kept out of the forces for the purpose of working assiduously and those not doing so will not be allowed to remain reserved But the specific proposal that military enlistment should be regarded as a penalty for industrial offences is open to objection and it would not meet with the support of the workers, nor, it might be added, of the armed forces themselves

Transport difficulties and the measures needed to overcome them are discussed at length The arrangements for supplying food to the workers are described and the Government cannot accept the recommendation that the Factories (Canteens) Order 1940, should be applied to all factories doing work for the Crown, and not only those employing more than 250 people For the smaller factories the policy is to establish British Restaurants nearby and the workers can either go to them or have meals sent to the factories The committee pointed out in their report that speeches congratulating workpeople on their efforts make for complacency, but the Government says there is no need to stimulate them to greater output on the basis that their best efforts have been feeble and unsatisfactory It probably should have been stated more definitely that if a worker is praised he will respond and will not become slack because he has been made to feel that he has done his best There are varying types of complacency or states of euphoria Report answers report on the whole satisfactorily and shows that constructive thought is being given to constructive criticism

Infectious Disease in England and Wales

WEEK ENDED NOV 8

Notifications —The following cases of infectious disease were notified during the week smallpox, 0, scarlet fever, 1366, whooping-cough, 2029, diphtheria, 1069, paratyphoid, 31, typhoid, 12, measles (excluding rubella), 747, pneumonia (primary or influenzal), 731, puerperal pyrexia, 108, cerebrospinal fever, 113, poliomyelitis, 33, polio-encephalitis 4, encephalitis lethargica, 3, dysentery, 148, ophthalmia neonatorum, 84 No case of cholera, plague or typhus fever was notified during the week

The number of civilian and service sick in the Infectious Hospitals of the London County Council on Nov 5 was 1315, including scarlet fever, 166 diphtheria, 298 measles, 23, whooping cough 505, enteritis, 32, chicken pox, 28 erysipelas, 22, mumps, 5 poliomyelitis, 6, dysentery, 23, cerebrospinal fever, 22, puerperal sepsis, 8, enteric fevers, 45, german measles, 1, other diseases (non infectious), 62, not yet diagnosed 69

Deaths —In 126 great towns there were 1 (0) death from enteric fevers, 1 (0) from scarlet fever, 1 (0) from measles, 2 (0) from whooping-cough, 24 (6) from diphtheria, 41 (2) from diarrhœa and enteritis under 2 years and 20 (0) from influenza The figures in parentheses are those for London itself

Bristol reported 1 death from an enteric fever There were 3 fatal cases of diphtheria at Liverpool

The number of stillbirths notified during the week was 164 (corresponding to a rate of 32 per thousand total births) including 13 in London f Government policy urging better organisation and ore speed in work The essence of victory lies in peed in audacity in taking risks and in dauntless ourage Unless the Government can supply these irtues they will, in the opinion of the country, have utstayed their welcome ' Mr Lloyd George went over o Shinwell after the speech and congratulated him— Conservative, Liberal and Labour M Ps did so too Mr A V Alexander s reply to the debate in which he dealt largely with Shinwell was on lines of personal attack and produced a bad impression on the House and he passed over the big questions raised by other members without remark

* * *

The Prime Minister had stated earlier in the day that a full debate on the address might if desired, extend over 2 or 3 weeks Parliament is awake and a succession of debates on big issues of policy is certain Mr Churchill does not now propose to make any changes in membership of the Government

Obituary

HUGH MORELAND McCREA

OBE MD RUI

By the death of Hugh Moreland McCrea a very remarkable man is lost to our profession The qualities in the aggregate required to make a great clinical physician are much more rare than those needed to make a great surgeon for the problems presented to the latter are solvable chiefly by touch sight and personal dexterity whereas those with which the physician has to cope require not only the piecing together in order of importance of a number of data obtained from various sources but the correct deduction from the whole assemblage

Vandyk

The power of doing this varies with individuals, but from time to time men appear who possessing a faculty for retrieving and marshalling in surprising context impressions latent in subconsciousness have it in remarkable degree The term *flair* is commonly used to describe this faculty and McCrea was one of those gifted persons To the gift was added an insatiable zest for professional knowledge which was continually added to by acute observation and voluminous reading The result was a many sided physician without one weak facet so that whatever the nature of the case he brought to it the ability of an expert on that particular malady He was at first in general practice surely the best of all preliminary schools for a career of pure medicine but like certain other great physicians who began that way the call to consulting work at last assumed imperative proportions His outstanding professional qualities became so widely recognised that he may justly be termed the consultant s physician, so many of them were numbered amongst his patients

His energy and kindness matched his abilities, for he threw his whole heart into every case great or small to which he was called and a multitude is in his debt His passing enhances a regret often felt before that he was never on the staff of a teaching hospital where the high ideals and deep mine of clinical lore of which he stood possessed could have been passed on to the younger men coming after him Amongst those of us who knew him he will always be remembered as a beloved physician and an unfailing help in time of trouble

V B

McCrea was born in 1877 at Belfast, where his father was a medical man of considerable distinction and his maternal grandfather was Dr R Dill, professor of midwifery at Queen's College He was at school at the Royal Academical Institution before entering Queen's University on a science scholarship He took the Malcolm exhibition and the Coulter clinical scholarship qualified M B in 1901 and for two years held resident appointments at the Royal Victoria Hospital In 1903 he settled in general practice at Wargrave, whence he moved to London four years later He combined a rare acumen with a profound knowledge of modern tendencies and of the various branches of medicine He was specially familiar with the many problems which ophthalmology presents to the practitioner of medicine and the ophthalmoscope revealed much to him which would have been hidden to many He was for long on the outpatient staff of the Paddington Green Children's Hospital and during the last war acted as senior physician to the City of London Military Hospital He became chairman of the Final Medical Appeal Board and he organised the emergency medical corps under the auspices of the Royal Society of Medicine For these services he was made O B E

The idea of forming a vast private hospital where private patients would have at their service the same advantages as those enjoyed by patients in the voluntary hospitals early took root in his mind and soon after the war finished he set about, with indomitable energy to realise his dream The result was the London Clinic of which he was the originator and principal promoter When in the years to come such institutions have grown up in all the great centres of population working either independently or in association with the voluntary hospitals it should be remembered that McCrea pioneered the way

For some time his health had given rise to anxiety but the end came on Nov 8 with unexpected suddenness He married Kate Rose, daughter of Charles Hannen of the Chinese Customs, and leaves his widow with two daughters

MILLICE CULPIN

LRCPE

Dr Millice Culpin, who died at Brisbane on Sept 1 at the age of 95, was Queensland s oldest doctor He was born in this country and began his schooldays at Alleynes Grammar School Stevenage, shortly before the outbreak of the Crimean war He qualified L S A. from the London Hospital in 1877 and took the Scottish conjoint qualification five years later He set up in practice in Brisbane over sixty years ago and soon all his interests were centred in his new home · except for one holiday many years ago he never returned to England He represented Brisbane in the federal parliament from 1903 to 1906 but public life was to him a duty, faithfully performed, and his real interests were his work, his books and chess He was also a member of the Rationalist Society of Queensland Dr Culpin leaves three daughters, and his two surviving sons are both members of the medical profession—Prof Millais Culpin of London and Mr Ernest Culpin of Brisbane

---

TRAINING THE LUFTWAFFE DOCTOR —The medical officer of the Luftwaffe seems to be a true son of the winged Hermes for he is trained to be both doctor and flier (*Dtsch med Wschr* Sept 12 1941, p 1018) After taking his Abitur—which is the equivalent of our matric—the candidate does six months' military training before joining the medical academy of the Luftwaffe which is at present housed in a suburb of Berlin Here he is taught the principles of aviation and at the same time begins his medical studies But his military training also continues and is considered an important part of his curriculum, for in spite of the Geneva convention the German medical officer ' often has purely military tasks of leadership to fulfil " So that he may lead medical flying units and cope with the problems of aviation medicine and flying in high altitudes the student must himself learn to fly gliders and planes and he must be able to manage not only the larger types of aircraft used for the transport of casualties but also the smaller makes such as the " Storch " and ' Weihe,' for they have the advantage of being able to land in a confined space He is also taught to use a parachute, for if he joins a company of paratroops he must be able to jump with his men Institutes for research in aviation medicine have been set up in Hamburg Freiburg-i-Br Jüterbog and Berlin animals and elaborate precautions taken to ensure that they duly consumed the syrup Whether it will do them any good we are not yet in a position to say, it can scarcely do them much harm, unless some of the "sharp, stiff hairs" have eluded us But, almost irrespective of the outcome, we have come to the conclusion that the game is scarcely worth the candle and that the chief virtue of our essay in rose-hip extraction lies in its significance as a gesture of benevolent interest We have had much the same feeling about the outcome of our attempts to grow oats and potatoes, but in war-time we do, with the official blessing, many curious things Rose-hip jelly as a jelly may be quite good, even appetising, but the treatment of rose-hips on the domestic hearth as a source of vitamin C seems to be rather an overrated amusement

* * *

After several false starts traceable to the water-pipes or to the singing of high-spirited colleagues and military policemen Wailing Willie really got going the other night, warning us of the unpleasant proximity of Hitler's young friends Our siren is no ordinary one Its voice is well and truly broken and in full cry resembles a byre at milking time or the ear nose and throat ward on tonsil morning Like the heating system its efficiency depends on the steam pressure and varies accordingly When the fires are banked up well and there is no other claim on its motive power its roaring is echoed and re-echoed from the hills like the wail of the last of the banshees, but on one famous night when the fireman had fallen asleep and let the furnace go down, all that Willie could do was to give an apologetic gurgle such as follows removing the stopper from a bottle of flat ginger beer As ill luck would have it that very night the all-clear came within five minutes and the raiders-past signal lacked its usual triumphant ring

The garb in which the various members of the staff parade on such occasions is to me a never-ending source of interest and amusement I myself am sufficiently hidebound in the fetters of convention to regard the absence of a collar and tie as the last infirmity of noble mind and dress accordingly Such opinions are not held by my colleagues The Physician, as all good physicians should, upholds similar ideals to my own but the very fountain head of orders has been known to appear wearing a lounge suit on top of his pyjamas, in extenuation, however, it must be said that the occasion in question was the third of three successive nights Some version of engineers' dungarees which our female friends assure us is termed a shelter-suit seems to be favoured by the junior members of the medical staff of that sex and I have found it in my heart to envy them when searching half asleep for a lost collar-stud at two in the morning The nursing staff, however, are allowed no such easily put on garment, but they are probably well used to dressing in the earlier stages of coma at 6 30 A M and little deserving of our sympathy They at least can put a cap over their curlers when rudely awakened, but the mere male who appears with untidy hair is frowned on by all alike

The wail of Willie is the signal for action stations for the fire-watching parties, who proceed armed with stirrup pump and sand to their appropriate places The selection of one's appropriate locus is not as simple as it sounds since our firemaster, one Sir Thomas Tucker, erstwhile leading light of the brigade in a provincial town, has an engaging habit of changing this about once a week without notice He has even been known to go off on holiday and take his beloved stirrup pumps with him for a change of air It is true he left us the hoses but according to his own teaching these are an invention of the devil only to be used by experts (for which read "himself") Despite these interesting diversions it is always with a grievance that I leave my warm and comfortable bed to watch for incendiaries which never fall or to shelter from high explosive dropped fifty miles away

---

MESSRS T J SMITH and NEPHEW have issued a second edition of their booklet "The Preparation of Plaster Casts," which includes patterns and directions for a spinal jacket in addition to the six plasters described in the first edition The booklet can be obtained free of charge, and a set of master patterns made of stiff paper is supplied with the first order for wide "Cellona" material

Parliament

ON THE FLOOR OF THE HOUSE

MEDICUS M P

ON Nov 11 Parliament was prorogued It quote Hansard, "End of the Sixth Session (opened November 1940) of the Thirty-Seventh Parliament United Kingdom of Great Britain and Northern in the Fifth Year of the Reign of His Majesty George the Sixth" But it was only a winding Nov 11 in order to open a new session on Nov 12, Speaker suggested that the custom of all filing past him, shaking his hand and bidding farewell, should be dropped "On this occasion I you farewell from this place and hope soon to again"

The King's speech on the prorogation of Parl referred to the Atlantic Charter as "a beacon in radiating resolution, justice and unselfish purpose" to conferences with the prime ministers of C Australia, New Zealand and South Africa The speech on the opening of the new session on Nov referred to consideration of "the urgent problems will face them when the nations now enduring tyranny of the oppressor have regained their freedom and further welcomed the restoration of the Emperor Ethiopia to his throne as the first country to be liberated and re-established

The content of these two statements of policy do not satisfy the House of Commons There is a widespread feeling that changes in policy are required—with regard to production for war purposes, with regard to the direction of our military efforts, with regard to interference with individual liberty centring round the use of the powers of Defence Regulation 18B, with regard to the allowances of wives, children and other dependants of men in the forces All members support the war effort of the Government but many think it should be intensified and that it should take cognisance of those larger issues of political and economic change that loom in men's minds in prefigurement of the future Sir Richard Acland, the wealthy landowner who is serving in the ranks in an Army Unit, emphasised these larger issues Contrasting this war and the last he said, "In this war there is a positive and passionate longing on the part of the overwhelming majority of the people not to go back to the miserable world which they knew in 1939 We want to move on to a new way of living where the motive of service will transcend the motive of individual gain" Acland referred to a meeting he had had with a very "tough set of successful business men" who all wanted "a Britain without property owners" and ended by what was in effect an appeal to Winston Churchill to take the lead in a complete renewal of Great Britain's economic and social structure

* * *

Major E E Gates, in a well-delivered maiden speech dealing with the anomaly of the difference in pay between the services and industrial workers, ended, "Unless the Prime Minister devotes himself closely and immediately to our pressing domestic problems with the same brilliancy that he has so far devoted to the grand strategy the war may be lost in these islands"

Mr Austin Hopkinson said this war was "really Armageddon" and that it would from the biological point of view decide the future progress of the human race He regarded the present war as the climax of human history and as embodying the conflict of principles which had been perceived clearly for 3000 years "In one country after another, in Northern India, in Greece and finally in Palestine one man after another has arisen and said that the whole human race is going to ruin—and that until men really believe, and act upon the belief, that it is better to give than to receive, there is no hope whatsoever for the future of humanity"

* * *

Mr D N Pritt, K C, criticised the continued presence in the Government of men who were "extremely lukewarm" towards our alliance with the U S S R Mr Shinwell reaffirmed the essential unity of the nation and our determination to effect the speedy destruction of Hitlerism but made a powerful and sustained criticism ough maternal tissue and so it may be said that the cental surface is sealed in such a way as to prevent s of blood through the separated placental surface it where such a very thin covering is involved there is und to be much tearing and it is likely that the herence of this thin maternal remnant does little to event loss of fœtal blood Personally I believe that e cord should be tied at once in order to conserve the tal blood-volume

Dundee   A E CHISHOLM

WHAT'S IN THE LOAF?

SIR,—Your timely leader discloses a situation nearly credible but so obviously in accordance with the ugly cts that further action is required

When the Medical Research Council issued their emo on national flour last spring it was understood that it contained the specification of national heatmeal flour which we were asked to eat Any oubts about this were dispelled when Lord Woolton ddressing the bakers at their national conference at eicester in June, said he had been at great trouble over he bread question but had been "advised by the most minent scientists in the country" and mentioned the Iedical Research Council by name in this connexion Everyone understood that one of the two 85% extraction lours specified in that memo was a specification of the wheatmeal bread to be introduced by the Ministry of Food It did not matter which, the millers were or their convenience to make one of these and then pass on to the other No other specification was issued nor ny information given by the Ministry of Food casting ny doubt; we knew what national flour was to be The specification was therefore examined and found good, especially when reports were issued by various nutritional laboratories as to the B vitamins minerals, &c this flour could be relied on to supply I therefore started a campaign to popularise wheatmeal bread explaining to patients how they would thus get a generous supply of the essential B vitamin as well as four times the anæmia-preventing iron they got from white flour How by this means the Ministry had made a cheap protective food available That it contained even less indigestible fibre than white and would be more digestible I was confirmed in these views when Circular 2470 was received from the Ministry of Health in June This was sent to me in my capacity of M O to the local infirmary and asked me to make the new bread available to patients and staff This circular is so illuminating that I quote one passage in full

> "The Minister has been in consultation with the Minister of Food on this matter and he is advised that national wheatmeal flour is now available to bakers This flour contains the greater part of the germ of the wheat, with some of the finer bran, but excludes the coarser bran It thus contains not only most of the vitamin B_1, but also most of the remainder of the vitamin B complex, as well as valuable minerals removed in producing white flour National wheatmeal flour is therefore of high nutritional value and is particularly valuable at times when there is restriction upon the availability of other foods from which these vitamins and minerals could be obtained."

Can anyone doubt that the flour specified by the Medical Research Council was under consideration? There was no other published, or known, and the reference to the fineness of the fibre left in is itself sufficient evidence if any were needed You now call attention to an order of the ministry regulating what national wheatmeal flour really is to be, and which was issued only two months after the consultations between the ministries on the same subject As you explain it this order simply makes fun of what the Minister of Health was told Or perhaps I had better say of what he informs us he was told by the Minister of Food Instead of containing the greater part of the germ of the wheat the flour need not contain any Instead of containing most of the B_1 vitamin it need not contain more than white flour from which most of it has been removed Instead of containing most of the remainder of the B complex this will be absent as will the valuable minerals For it may be nothing more than white flour to which some bran has been added!

So all that I have been telling patients, on the word of two ministries, has been without justification I object to being misled at any time, but particularly on a matter of such importance to us all in war-time

It will only be fair to the M R C if I state that a letter from the council informs me that the policy of the country as regards the production of white and brown bread is decided entirely by the Ministry of Food and that they have nothing to do with this, the letter concludes (italics mine). "No doubt, IF the Medical Research Council had to give advice *without taking into consideration any other body*, they would recommend 85% extraction flour with added calcium" Compare this situation with that at the Air Ministry and ask where we should be today if Sir Archibald Sinclair had adopted the same attitude towards his scientists and left planes to be made in ways giving most profit to manufacturers Because can anyone doubt that financial interests have a connexion with the change of front on wheatmeal? Or is it simply the dullness shown by the previous representative of the Ministry of Food in the House of Commons who declared there "We want no scientific stunts on the Kitchen Front"? The Ministry of Food have able men who understand nutrition at their service Why are they not being used?

All should be grateful to you for raising such a vital though unpleasant question

Grimsby   S W SWINDELLS

PERINÆAL SUTURE UNDER LOCAL ANÆSTHESIA

SIR,—In your annotation last week (p 611) you rightly emphasise the value of repair of the perinæum under local anæsthesia and refer to a paper by B Williams and to another by Neal Smith, the latter reporting its use with good results in 17 cases at Charing Cross Hospital Thirteen years ago in your columns (*Lancet*, 1928, 1, 1281) I described an exactly similar method even to the insertion of the needle through the skin surface and stressing, as Dr Smith does, the importance of infiltrating the tissues immediately under the skin or mucous membrane The only difference between Dr Smith's method and mine, so far as I can see is that I advised the addition of adrenaline chloride solution (1 drop of a 1 · 1000 solution to each drachm of Novocain) and pointed out that it spared the patient any pain from insertion of the needle if a swab soaked in the solution was placed for 5 minutes beforehand against the raw surface The method as described by me has since been in routine use by the students and staff in the obstetric unit of University College, both in the hospital and on the district, and during these 13 years it must have been used in several thousand cases The results have been so uniformly satisfactory that no one has suggested that it should be discontinued To my knowledge the method is now routinely and successfully used in at least three other London hospitals

University College Hospital, W C 1   F J BROWNE

STUDENT AND SCREEN

SIR —The comments in your issue of Nov 8 draw attention to the neglected possibilities that lie in the film for teaching medical students The increasing amount that has to be learnt in a limited time makes it surprising that no request for use of films has yet been made by medical students Though academic circles in this country have hardly noticed this weapon there are a number of good scientific films that could be more widely used in teaching—films on mathematics, physics chemistry biology anatomy and physiology and films illustrating operative technique in surgery and obstetrics Medicine has not yet been filmed so much though the film on malaria which you reviewed is of very high quality. There are films on subjects ranging from oxygen therapy to the treatment of war neuroses, there are health education films for children and adult audiences, and the relation of medicine to the community is illustrated in films such as the British Commercial Gas Association's excellent nutrition film "Enough to Eat," and the Ministry of Information film "Health in War."

The chief reason why a wider use has not yet been made of available films is probably ignorance either of their existence or of how to get hold of them The Scientific Films Committee of 30, Bedford Row, W C 1, have viewed a large number of scientific films and are continuing to do so A list of scientific films with an independent evaluation of their merit for showing to

Letters to the Editor

WORKING HOURS

SIR,—In September, 1915, Mr Lloyd George, then minister of munitions, appointed a Health of Munition Workers Committee, "to consider and advise on the question of industrial fatigue, hours of labour and other matters affecting the physical health and physical efficiency of workers in Munition factories and workshops" The committee recognised that if men are asked to work for fifteen hours a day for weeks and months on end, as was the case in 1916, one of two results must follow, either the health of the workers will break down or they will not work at full pressure In either case output must suffer The committee made the provisional recommendation that hours of work for men should not exceed 65–67 per week, for women and girls 60, with no night work for girls under eighteen, and for boys under sixteen, 60 hours with no night work In 1917 the committee stated that they were convinced that the maximum limits of weekly employment provisionally suggested were too high except for quite short periods and that the time was then ripe for a further reduction in the hours of work They were satisfied that reduction could be made with benefit to health and without injury to output

It is some 120 years since Robert Owen ran his New Lanark Mills for only 10½ hours a day instead of the usual 15–16 and found that output did not sensibly fall below its previous level, while there was marked improvement in the cheerfulness of the operatives and in their vigour The events of the last war demonstrated beyond question that there was a point beyond which it was folly to extend hours of employment and that that point was much lower than had been accepted previously Subsequent work carried out under the auspices of the Industrial Health Research Board has all pointed in the same direction Vernon in his book "The Health and Efficiency of Munition Workers" suggested that the optimum working hours for women are between 48–54 per week, and girls under 18 should not be required to work more than 48 hours per week It is only after two years of war that these well-established principles have received some measure of official sanction The Government comment on a recommendation in the 25th report of the Select Committee on National Expenditure, issued recently recognised that investigations by the Industrial Health Research Board have established that, over an extended period, weekly work hours should not exceed 60 for men and 55 for women, and the Government is satisfied that it is more useful to restrict weekly hours now within the limits mentioned than to make further investigations It is officially agreed that, to maintain maximum production, Sunday work should be abolished in industry, except to meet the most compelling emergency and except in those plants where workers have a break of at least 24 hours per week under a rota or relief system

It is a matter for profound regret that it has taken so long to relearn such an essential lesson of the last war, and it is to be hoped that never again will there be a temptation to succumb to some of the follies in this matter of working hours that have been perpetrated during the last two years

DUNS SCOTUS

PNEUMOCOCCAL MENINGITIS

SIR,—So many reports of the recovery of isolated cases of "pneumococcal meningitis" have now been made that one would gain an impression that the outlook had very materially altered since sulphapyridine was introduced I am sure there must be many clinicians like myself who feel that this scarcely reflects the true state of affairs, and who are therefore grateful to Dr Cooke for his significant paper in THE LANCET of Nov 1

There are two observations I would like to make on your annotation of Nov 8 When assessing the results of treatment is it satisfactory to lump all cases under the generic term of pneumococcal meningitis? My own experience leads me to subdivide those cases into three groups First the *septicæmic case* where meningitis is a late, often terminal, complication of a pneumococcal infection distant from the meninges, second, the *invasive case* where meningitis is a result of local spread from a focus of infection close to the meninges, third, the *traumatic case* where the infection is by the passage of organisms from the nose or through a breach of bone (this last the postoperative case) Such a subdivision has, think, considerable importance in relation to therapy Septicæmic cases occur even during the of sulphonamide therapy, and presumably this that either the organism is insusceptible to the drug or the patient is unable to utilise it, the fatality-rate in this group is still high In the invasive case sulphonamide therapy may, for the time, discourage further invasion, but will almost certainly not eradicate the primary focus for which surgery will still be required if recurrence of the meningitis is to be prevented In the traumatic case, however, sulphonamides may be expected to show optimal results, for the organism is here probably of low virulence and its invasiveness may therefore be promptly checked The clinician's assessment of the value of chemotherapy will thus depend on the kind of case he is called on to treat

My second point is to ask for the evidence which supports the statement that type III is the most common single type in this infection" I cannot recollect having seen a single type III infection of the meninges My earlier records are unfortunately not readily available, but I have seen twelve cases since 1935 in which the types were II (4), V (1) VI (2), VII (1) XIII (1), XXIII (2) and one where the pneumococcus did not agglutinate with any of Cooper's 32 types None of these cases recovered despite the administration of sulphapyridine Only three of them did not belong to the septicæmic group The type VI was caused by an antral infection, while the type XIII was secondary to a mastoiditis There was no apparent primary focus in the case from which the untypable strain was obtained (It is at least arguable that the comparatively rare primary pneumococcal meningitis should be included in the septicæmic group) I can readily understand that type III, which is so often present normally in the nose or throat, might be most frequently encountered in the traumatic group but I can see no reason for supposing a high incidence of this type in the septicæmic or invasive group In these groups one would expect the type incidence to correspond to that peculiar to the district from which the cases were drawn

Knightswood Hospital, Anniesland THOMAS ANDERSON

WHEN TO TIE THE CORD

SIR,—I was interested in your leading article of Nov 8 on when to tie the cord It always seems to be taken for granted that the baby will gain extra blood if delay is made before applying the ligature until pulsation in the cord has ceased I suggest that this is contrary to the truth and that the baby is liable to lose blood by this delay In any case I think the following argument is worth consideration From the point of view of the welfare of the babies the matter is of importance It is obvious that the only force propelling the fœtal blood stream, and hence that part of it going to and coming from the placenta, is the fœtal heart beat This force is of only moderate power and yet it is the only force available for the return of blood from the placenta to the fœtus This is a great task for a comparatively weak organ to fulfil Intermittent uterine contractions during the third stage obviously can be of little or no account in this process Consider the work that the heart must do and the conditions prevailing The placenta is an inert body and is, in the third stage, largely unsupported Therefore, before any blood returns to the fœtus the placenta must fill up and form what is equivalent to a heavy lake of blood The fœtal heart must take on the strain of overcoming the resistance of this inert and heavy lake in order to force any blood at all back to the fœtus through the umbilical vein It is practically certain that the task is too great and that far more blood remains in the placenta than ever returns to the fœtus Thus the fœtus will lose more and more blood the longer the flow continues to go into the placenta But the fœtus may lose blood in another way as well There may be a certain amount of separation of the placenta and there may thus be direct fœtal blood loss through the separated placental surface It is true that anatomically the placenta separa

edical Society of London

A meeting of this society will be held at 11, Chandos Street, 1, on Nov 24 at 3 30 P M, when Dr John Parkinson will d a paper on heart attacks, Mr V E Negus on congenital ortening of the œsophagus, and Mr Guy Blackburn on gional ileitis

oyal Medico-Psychological Association

A meeting of this association will be held on Nov 26, at , Chandos Street, London, W 1, at 2 15 P M,, when Dr Lilian Hutton will read a paper on the investigation personality in patients treated by prefrontal leucotomy

iochemical Society

A meeting of this society will be held at the Courtauld nstitute, Middlesex Hospital London, W 1, on Saturday, ov 29, at 11 A M., when Dr G M Findlay will open a dis-ussion on the modes of action of chemotherapeutic agents

edico-Legal Society

A meeting of this society will be held at 26, Portland Place, ondon, W 1, on Thursday, Nov 27, at 4 P M, when Dr I Neville Stafford will read a paper on the coroner and ivilian war deaths

ocialist Medical Association

At a meeting of this society on Saturday, Nov 22, at 12, Great Newport Street, London, W C 2, at 2 30 P M, Sir Albert Howard and Mr Frederick Ridley, F R C S, will speak on griculture and health

War Wounds Committee in Scotland

The Medical Research Council has set up in Scotland a sub ommittee of their war wounds committee The members are Prof J R Learmonth (chairman), Dr A B Wallace (secretary), Prof J S Young, Prof R C Alexander, Prof D F Cappell, Prof C F W Illingworth, Prof C H. Browning, Dr D P Cuthbertson, Sir John Fraser, Prof T J Mackie, Mr C P Stewart, Ph D and Dr J M Johnston

Domestic Staff in Hospitals

In recognition of the national importance of domestic work in hospitals the Minister of Health has decided to issue a badge to all those employed on domestic work in hospitals, who give at least 96 hours regular service each month Women who are whole time hospital helpers on registration will not be called for interview

Calls to the Bar

On Nov 17 the following were called to the bar Lieut Colonel Ralph Brooke, F R C S, R A M C (Inner Temple), Dr F H Blackburn and Mr E A Butterworth, F R C S (Middle Temple), and Dr A. P Cogswell (Gray's Inn)

Control of Scabies

The Minister of Health has issued a new regulation giving medical officers of health authority to inspect premises in which verminous people have been accommodated and to examine and treat other people on those premises They may also order the cleansing or destruction of articles on the premises

International Hospital Association

At 2 P M on Nov 25 at B M A House, Tavistock Square, W C 1, the United Kingdom council of this association will hold a conference to discuss the position of hospitals in the post war world Prof A T Jurasz, dean of the Polish medical faculty in the University of Edinburgh, will read a paper on the international position of hospitals after victory and the coming of peace Representatives of 54 countries have been invited to attend, and the Minister of Health will be present Admission will be by special ticket only, and further information may be obtained from the hon secretary, 17, Bloomsbury Square, London, W C 1

Anglo-Soviet Medical Committee

The aims of this committee are to form a liaison between the medical professions of Great Britain and the U S S R to exchange the latest clinical and scientific knowledge, to facilitate visits of medical specialists between the two countries, and to give specialist advice on medical aid to the U S S R It is proposed to make the minimum annual subscription for associate members 5*s* A bulletin on the committee s work will be issued from time to time and a general meeting will be held early in the new year Those who wish to become associate members should write to the hon secretary of the committee, 1, Wimpole Street, London, W 1

Notes, Comments and Abstracts

HOME VISITING OF DEFAULTING VENEREAL-DISEASE PATIENTS

J L BURN, M D DURH., B HY, D P H
MEDICAL OFFICER OF HEALTH, CITY OF SALFORD

A NOTE of a year's working of a scheme of home visiting of defaulting female patients who had attended a venereal-diseases clinic may be worthy of record Only women and children were followed up, these consisted of female patients who had defaulted in attendance at the venereal-diseases clinic of the county borough of Barnsley and some special cases referred thereto All the defaulters (some of whom had not been seen for some years) had received several invitations by letter to attend, and up to the time of the visit all these letter-invitations had proved ineffective It is considered that the number who would have returned to the clinic without a visit would have been negligible

The home visiting was carried out by a health visitor who also acted as a part-time nurse in the venereal-disease clinic, and part-time health visitor in the maternity and child-welfare service An advantage was that the visitor was not "known" to patients or public as a venereal-disease visitor Additionally, her position enabled close liaison to be maintained between other health visitors and medical officers of the maternity and child-welfare and school medical services The visiting—which was done with the aid of a car—occupied time equivalent to one session only per week, thus, for the year's working, the number of sessions occupied in home visiting was under 50

In all, 163 persons were visited The medical diagnoses on the case sheets of the persons visited were syphilis or ? syphilis, 105, gonorrhœa or ? gonorrhœa, 38, non-venereal disease, 20 The total number of visits paid was 305 92 persons were visited once; 28 persons twice, 23 persons three times, 15 persons four times, 3 persons five times, 1 person six times, and 1 person seven times Of the 163 persons, it was found that 26 had removed and 3 had died, leaving a net total of 134 Of these, over a third (i e 50, or 37% of the total) attended regularly, while another 16 attended more or less regularly

On visiting several clinics throughout this country, I was impressed by the fact that some of the most dangerous types of patients from an infective point of view are young people who default after a few attendances—this despite the fact that the patients were handled with the greatest tact and efficiency In each case, verbal promise had been obtained to continue attendance until cured It is always easy to elicit promises in the clinic Follow-up letters had proved of no value

In addition to the problem of defaulting, the problem of untraced contacts is serious—only 10% of the wives or partners of infected patients on an average were traced These facts are full of danger to the public health, and make consideration of the help which home visiting can give more urgent

Figures quoted in the excellent booklet of the British Social Hygiene Council, "Notes on Social Service in the Treatment Centre," are very striking At St Mary's Hospital, Paddington, the proportion of defaulters in the total number of patients is now as low as 6%, owing in large measure to the work of the almoner, described in Miss Dorothy Manchee's book "Social Service in the Clinic for Venereal Diseases" (London, 1938) At Guy's Hospital, the percentage of defaulters who were induced to return rose in six years from 46% to 80% At the corporation V D department in Edinburgh, among the women and children patients, 9 out of every 10 defaulters were persuaded by the nurse's visits to return and continue treatment In 1921–22, before the appointment of a nurse-almoner, the defaulter rate was 54%, in 1937 it was 8 5%

The appointment of a fully trained almoner of the right personality is undoubtedly ideal, but many clinics are too small for the whole-time employment of an almoner, and there are not sufficient trained almoners to go round The task of persuading committees to make expert and to general audiences and for teaching purposes has been prepared Detailed critiques of these films and their contents are also available The S F C has arranged a number of film shows at the request of various medical societies, and also shows of health films (similar to the public health show given by the London Scientific Film Society last winter) for more general audiences It is important that films should be used widely in the health education of the public, and a start has been made with "Defeat Diphtheria" and "Breath of Danger," The committee will be glad to give information to those who wish to know more about or to arrange shows of films of medical interest

London, W C 1 RONALD MACKEITH

DISPOSAL OF STILLBORN CHILDREN

SIR,—The sequel to the story of your peripatetic correspondent, or one like it, about the fœtus in the abdomen of a man, was that the mortician rather unnecessarily reported it to the coroner As the body had been removed some miles away from the hospital the coroner was concerned that the body should have got into his jurisdiction and did not quite know what to do about it So he reported to the Home Office who sent one of the Big Five from Scotland Yard to see me on a Sunday morning to suggest that the mortuary keeper had been aiding and abetting the offence of concealment of birth. Of that it was shown that he was not guilty However, the chief inspector's visit was followed by a documentary admonition to which I was able to reply that the procedure of placing a baby's body in the coffin of an adult had written authority from the Home Office, given some years before Whereupon there was some flutter in the official dovecote The hospital changed its procedure but the disposal of stillborn children still gives trouble

REGIUS PROFESSOR OF MIDWIFERY IN THE UNIVERSITY OF ABERDEEN, OBSTETRICIAN IN CHIEF TO THE ABERDEEN MATERNITY HOSPITAL

JOHN F B WYPER,
M B GLASG, B SC
RESIDENT REGISTRAR AT THE HOSPITAL

IN his book "Poverty and Population"[1] R M Titmuss quotes an estimate made by Dr Enid Charles that if fertility remains at its present level the population of England and Wales will decline at the rate of 24% in each generation, so that on the basis of the 1931 census the number of children in 1945 will have decreased by 25%, and the number of people over 60 will have increased by 36%. Titmuss also quotes Glass who points out that in England and Wales there are great regional differences in fertility. The birth-rate of the south of England is much lower than that of the north and Wales. If the rates for the south-east had operated in the north and Wales during the decade ending 1936 our child population would have been reduced by about 250,000. Titmuss holds that it is illogical and inefficient to contemplate inducing people to have more children until we have judged the extent of contemporary waste in human life, for though it is only the higher fertility-rates in the north of England and Wales which are saving the country from a more rapid and disastrous decline in population, it is exactly in these areas that the infant mortality is highest. For example, in 1935 the infant mortality for Jarrow was 114 per 1000 live births as compared with 32 per 1000 for Coulsdon and Purley. Social conditions in Scotland are on the whole worse than in England, and there are similar variations in fertility so that the same conclusions can be drawn. The infant death-rate in Scotland in 1940 was 78 per 1000, for England and Wales it was 55 per 1000. It is obvious, therefore, that in Britain today many infants are dying who should not do so.

It has been recognised for some time now that the infant mortality is largely dependent on poverty and its resulting low standard of living. That neonatal mortality also depends on social conditions is suggested by the figures published by McNeil[2] who showed that in 1937 the neonatal mortality in Scotland was 38 per 1000, in the north of England 34 and the south-east 24. Comparing cities he showed that the rate for Glasgow was 43 per 1000 for Greater London 24, Chicago 25 and Amsterdam 16.

Less information is available about stillbirths, these were notifiable for the first time in Scotland in 1940, where the rate for that year was 42 per 1000 and for England and Wales 36 per 1000. Since most neonatal deaths are directly connected with pregnancy or child-birth, it is permissible to add them on to the stillbirths to get some idea of the number of children who reach the stage of viability and yet die as a result of some complication of pregnancy, labour or the puerperium. In Scotland during 1940 the figure was 80 per 1000 births, this seems a dangerously high figure, especially when taken in conjunction with the falling birth-rate.

Before one can give any opinion as to how the figure can be lowered it is important to study the actual causes of death in detail. This can only be done in hospital where records are detailed and an autopsy is usually carried out. With this end in view, we have analysed the stillbirths and neonatal deaths occurring in the Aberdeen Maternity Hospital during the years 1938–40 inclusive. The cases were divided into booked cases and emergency cases.

MORTALITY IN BOOKED HOSPITAL CASES

There were 93 stillbirths (27.1 per 1000) among the 3427 booked cases. In 49 the child was mature and in 44 premature. Among the full-time cases there were two main groups. In the first group (19 cases) no adequate explanation could be found to explain the stillbirths, the fœtus died before the onset of labour or during the course of an easy labour and in some of these a small tentorial tear was found with or without intracranial bleeding. In the second group (12 cases) trauma was the important factor and here the labour was difficult owing to breech presentation, prolapse of the cord or uterine dysfunction, the death of the child was understandable, being due to asphyxia shock or cerebral hæmorrhage. In the premature babies (44 cases) prematurity was the chief factor in bringing about the stillbirths. In some cases a pathological condition of the mother was present (pre-eclampsia in 6 cases debility in 5, placenta prævia in 4, accidental hæmorrhage in 3) but in almost half of the cases (19) no explanation for the premature onset of labour could be found. The stillbirth figure of 27.1 per 1000 births seems high but compares favourably with the stillbirth-rate of 39 per 1000 for the city generally and 42 per 1000 for Scotland as a whole. In the present state of our knowledge the figure cannot be reduced substantially.

During the same period there were 94 neonatal deaths among booked cases (46 full-time and 48 premature)—a rate of 27.4 per 1000 births. Causes of death in the group of full-time babies were infection 18 trauma 6, unknown 5 gross fœtal deformity 6 atelectasis 3 accidental hæmorrhage 1, placenta prævia 1, suffocation by overlying (after discharge from hospital) 3 miscellaneous 3. Among the 18 deaths due to infection, 16 occurred after discharge from hospital. As far as could be ascertained, 7 were due to pneumonia and 9 to gastro-enteritis. The 2 deaths in hospital were due to pneumonia. It appears therefore, that the risk of infection in full-time babies in a well-run maternity hospital is much less than in the home. Of the 6 deaths from trauma, 3 followed difficult labour and might have been avoided if cæsarean section had been done, the other 3 followed fairly easy labour.

The factors responsible for the onset of premature labour in the cases where death was associated with prematurity were as follows unknown 17 debility 7, pre-eclampsia 5, twin pregnancy 8, eclampsia 3, accidental hæmorrhage 1, placenta prævia 3, gross fœtal deformity 2, miscellaneous 2. The important factor here again is the unknown one. In 17 cases no reason could be detected by clinical means to explain why labour came on prematurely. The actual cause of death in these cases may have been cerebral hæmorrhage, atelectasis, pneumonia or gastro-enteritis, but it was felt that the important predisposing factor was the prematurity.

The neonatal mortality for the City of Aberdeen is 33 per 1000 and for booked cases in hospital 27.4 per 1000, but if the deaths due to infection after leaving hospital and overlying are removed the figure falls to 21.3 per 1000. Any substantial fall below this figure could only be effected by the prevention of premature labour, this problem will be discussed later.

MORTALITY IN EMERGENCY CASES

During the years 1938–40 there were 187 stillbirths in 616 emergency cases—83 in full-time deliveries and 104 in premature cases. In the full-time cases the most common cause of stillbirth was a mechanical factor—difficult labour and placenta prævia (41 cases or 50%). Many of the deaths in this group could have been avoided by earlier admission to hospital. Pre-eclampsia in the mother, in some cases followed by accidental hæmorrhage, accounted for 24 stillbirths. Some of the deaths in this group could have been avoided by better antenatal care and earlier admission to hospital with longer rest in bed. There were no other groups of importance.

As regards stillbirths in premature babies, the biggest factor was toxæmia in the mother (50 cases or almost 50%). The other categories were accidental hæmorrhage without toxæmia 11 cases, placenta prævia 15, cause unknown 12. In these groups fewer of the deaths are avoidable. In some of the cases of toxæmia better antenatal care would have saved the child's life, but many were probably unavoidable, they include cases where the mother made a poor response to treatment, fulminating cases, and others where intra-uterine death of the fœtus occurred even where the toxæmia was apparently mild and responding well to treatment.

such an appointment is not easy, and it was with this in mind that I deemed it wise to proceed cautiously and utilise the services of a member of the health-visiting staff in the scheme described When the good results of such visiting are proved it will be simpler to persuade an authority to go ahead with the appointment of an almoner, or to join a group of authorities and thus to justify a whole-time appointment In dealing with so difficult a disease as venereal disease, which has social, psychological and moral complications and legal snags, it is essential to select a nurse of the right personality, discretion and power of persuading patients In nursing staffs of large health departments there is sure to be one or more who fulfils these conditions, and thereby a start can be made in this valuable work

VALUE OF HOME VISITING

It is claimed that the results of this small scheme are sufficient justification for the venture and the expense involved To get over a third of the defaulters to attend regularly is of decided value, but the results cannot be assessed merely by statistics Two individual cases are worthy of description

CASE 1 —A girl, aged 16, with acute gonorrhœa This acutely infectious case, living under bad home conditions, defaulted before completing treatment The visitor got to know her patient, and the mother's opposition melted before a simple explanation of the function of a special treatment centre The patient was persuaded to attend Again she defaulted Further visits resulted in regular attendance, and she was finally discharged cured In this case, the girl was put in touch with a girls' club, and it is believed that much social as well as physical good to her future life has ensued from the intervention of the visitor It is reasonable to assume that the possible consequences of this girl's defaulting would certainly have been a danger to herself, and probably to others

CASE 2 —A woman, aged 27, with congenital syphilis This patient suffered from interstitial keratitis and irido-cyclitis She consented to visit the clinic only after many visits had been paid, and the visitor arranged to accompany her to the clinic Subsequently, this patient defaulted, but after small personal problems had been dealt with treatment was continued more or less regularly Her eye condition dramatically improved This would not have been achieved if ordinary clinic methods of follow-up letters had been employed to secure further attendance

Only by means of visiting can the real reason of defaulting be discovered These patients are human—all too human There are numerous obstacles to attendance, some minor and absurd, but they are often easily overcome by right handling Weariness in attending, the wishful thinking whereby patients believe attendance unnecessary on the cessation of an obvious discharge, quarrels on the subject between husband and wife, ill health, the glib promise to attend given to the doctor in the clinic, the terror of discovery or losing a job, the threat to happiness, the guilty conscience or innocent shame—these factors, of enormous importance, show that cure of venereal disease is not entirely a medical problem

Home visiting was worth while in the case of mothers who had been treated antenatally Such patients are prone to default The birth of an apparently healthy baby convinces the mother that there is no further need to attend, while the added care of the baby renders attendance difficult In several cases the private practitioner was said to have informed them they that did not require to attend

Cases visited with the least success were those who live in " houses let in lodgings " and who frequently move from town to town Several such women suffering from acute gonorrhœa (living in the same house and having been infected by the same man) attended for a short time, defaulted, and when they were visited it is found they have moved on, leaving no address In one family where the children were congenitally infected the reason for defaulting given was that the journey to the clinic was too long This reason would never have been given in response to a letter, but could only be elicited on visiting the home In this case arrangements were made for the treatment to be given at a nearby school clinic

In several cases it was discovered that the times at which the clinic was opened were unsuitable It is of obvious importance for the staff in charge of a clinic to be acquainted with these deterrents, yet I do not see the staff can realise all the difficulties unless the which are gained from home visiting are known to t War-time difficulties of shift work, blackout, transport difficulties and increased female employment aggra the obstacles to attendance, and it is more than e important that these factors should be brought to light, so that the authorities can as far as possible make the clinics suit the patients, and make minor but nevertheless important improvements in clinic services

In only 2 cases were there definite refusals to discuss the question of attendance at V D clinics In 20 of the 134 the patients gave a definite refusal to attend, and the refusal was accepted Medical officers have the consolation of knowing that, at any rate, the patients have been warned, and that every expedient has been used to ensure attendance No attempt was made—nor was any necessary—to browbeat the patients into attending In many cases, simple methods of explanation, kindness and encouragement were all that were required to dispel ignorance and fear and secure cooperation

No attempt was made to solve the thornier problem of visiting defaulting male patients or contacts I know of no record of this work being done at all in this country On a pre-war visit to a Paris clinic I admired the ease and objectivity with which this work was done

The confidential nature of venereal disease treatment was preserved No legal difficulties were encountered. The scheme was economical—a useful point in persuading committees—the cost of the time of the nurse in visiting would not amount to more than £25 throughout the year This expense is small in view of the results obtained in the 2 cases quoted above, apart from the general fact that some attendance of nearly half of the patients who had defaulted was secured, while the attendance of over a third of chronic defaulters to the end of treatment and tests of cure was ensured

Very few venereal-disease clinics in this country use a home visitor to induce defaulters to complete treatment or to trace and treat contacts, yet I consider that the home visitor is an essential member of the team necessary to achieve greater success in this difficult work

I acknowledge the ever ready help and encouragement given by officers of the British Social Hygiene Council Any success which the scheme had is due to the personal effort of Miss Hilda E Myers of the Barnsley health department

REEVE TO THE L C C

THE mental hospitals committee of the council have always been farmers in a small way, for it was considered wise that patients at the mental hospitals of the council should where possible have a chance of doing healthy work in the open air, and farms were attached to several institutions Since the outbreak of the war the farmland of the council has been nearly doubled—today they farm over 5000 acres—and last July they asked the committee to undertake the general control of their scattered plots It therefore fell to the mental hospitals committee to present the report of the yield of the council's lands up to the end of March, 1941, though this was before they took over The committee explain that the drastic rationing of foodstuffs caused a fall in the number of eggs produced (359,000 in 1941 against 556,000 in 1939) Outbreaks of foot-and mouth disease reduced the number of cows kept and the milk production fell from 650,000 gallons in 1939 to 543,000 gallons in 1941 Next year, under the new scheme of coordination the committee hope to increase the production of vegetables, potatoes and animal foodstuffs by as much as 60%, 250% and 375% over their pre-war level of 1200 tons, 1000 tons and 1400 tons respectively If there should be a shortage of supplies the products of these farms will form a valuable pool of foodstuffs on which the claims of hospitals will be given priority

---

CORRIGENDA —The Minister of Health's request in circular 2498 (see *Lancet*, Nov 8, p 571) that tuberculosis notifications should reach him promptly was addressed to county councils and county borough councils The circular was sent to the other bodies mentioned for information only—In the summary of Major Palmer's article of Nov 8 (p 563) for " antitetanic serum " read " tetanus toxoid "

REGIUS PROFESSOR OF MIDWIFERY IN THE UNIVERSITY OF ABERDEEN, OBSTETRICIAN IN CHIEF TO THE ABERDEEN MATERNITY HOSPITAL

JOHN F B WYPER,
M B GLASG, B SC
RESIDENT REGISTRAR AT THE HOSPITAL

IN his book "Poverty and Population"[1] R M Titmuss quotes an estimate made by Dr Enid Charles that if fertility remains at its present level the population of England and Wales will decline at the rate of 24% in ch generation, so that on the basis of the 1931 census e number of children in 1945 will have decreased y 25%, and the number of people over 60 will have creased by 36% Titmuss also quotes Glass who oints out that in England and Wales there are great egional differences in fertility The birth-rate of the outh of England is much lower than that of the north nd Wales If the rates for the south-east had operated n the north and Wales during the decade ending 1936 ur child population would have been reduced by about 250 000 Titmuss holds that it is illogical and inefficient o contemplate inducing people to have more children ntil we have judged the extent of contemporary waste n human life, for though it is only the higher fertility-rates in the north of England and Wales which are saving the country from a more rapid and disastrous decline in population, it is exactly in these areas that the infant mortality is highest For example, in 1935 the infant mortality for Jarrow was 114 per 1000 live births as compared with 32 per 1000 for Coulsdon and Purley Social conditions in Scotland are on the whole worse than in England, and there are similar variations in fertility so that the same conclusions can be drawn The infant death-rate in Scotland in 1940 was 78 per 1000, for England and Wales it was 55 per 1000 It is obvious, therefore, that in Britain today many infants are dying who should not do so

It has been recognised for some time now that the infant mortality is largely dependent on poverty and its resulting low standard of living That neonatal mortality also depends on social conditions is suggested by the figures published by McNeil[2] who showed that in 1937 the neonatal mortality in Scotland was 38 per 1000, in the north of England 34 and the south-east 24 Comparing cities he showed that the rate for Glasgow was 43 per 1000 for Greater London 24, Chicago 25 and Amsterdam 16

Less information is available about stillbirths; these were notifiable for the first time in Scotland in 1940, where the rate for that year was 42 per 1000 and for England and Wales 36 per 1000 Since most neonatal deaths are directly connected with pregnancy or childbirth, it is permissible to add them on to the stillbirths to get some idea of the number of children who reach the stage of viability and yet die as a result of some complication of pregnancy, labour or the puerperium In Scotland during 1940 the figure was 80 per 1000 births, this seems a dangerously high figure especially when taken in conjunction with the falling birth-rate

Before one can give any opinion as to how the figure can be lowered it is important to study the actual causes of death in detail This can only be done in hospital where records are detailed and an autopsy is usually carried out With this end in view, we have analysed the stillbirths and neonatal deaths occurring in the Aberdeen Maternity Hospital during the years 1938–40 inclusive The cases were divided into booked cases and emergency cases

MORTALITY IN BOOKED HOSPITAL CASES

There were 93 stillbirths (27 1 per 1000) among the 3427 booked cases In 49 the child was mature and in 44 premature Among the full-time cases there were two main groups In the first group (19 cases) no adequate explanation could be found to explain the stillbirths, the fœtus died before the onset of labour or during the course of an easy labour and in some of these a small tentorial tear was found with or without intracranial bleeding In the second group (12 cases) trauma was the important factor and here the labour was difficult, owing to breech presentation prolapse of the cord or uterine dysfunction, the death of the child was understandable, being due to asphyxia shock or cerebral hæmorrhage In the premature babies (44 cases) prematurity was the chief factor in bringing about the stillbirths In some cases a pathological condition of the mother was present (pre-eclampsia in 6 cases debility in 5 placenta prævia in 4, accidental hæmorrhage in 3) but in almost half of the cases (19) no explanation for the premature onset of labour could be found The stillbirth figure of 27 1 per 1000 births seems high but compares favourably with the stillbirth-rate of 39 per 1000 for the city generally and 42 per 1000 for Scotland as a whole In the present state of our knowledge the figure cannot be reduced substantially

During the same period there were 94 neonatal deaths among booked cases (46 full-time and 48 premature)—a rate of 27 4 per 1000 births Causes of death in the group of full-time babies were infection 18 trauma 6 unknown 5 gross fœtal deformity 6 atelectasis 3, accidental hæmorrhage 1 placenta prævia 1, suffocation by overlying (after discharge from hospital) 3 miscellaneous 3 Among the 18 deaths due to infection, 16 occurred after discharge from hospital As far as could be ascertained, 7 were due to pneumonia and 9 to gastro-enteritis The 2 deaths in hospital were due to pneumonia It appears therefore, that the risk of infection in full-time babies in a well-run maternity hospital is much less than in the home Of the 6 deaths from trauma 3 followed difficult labour and might have been avoided if cæsarean section had been done, the other 3 followed fairly easy labour

The factors responsible for the onset of premature labour in the cases where death was associated with prematurity were as follows unknown 17 debility 7, pre-eclampsia 5, twin pregnancy 8, eclampsia 3, accidental hæmorrhage 1, placenta prævia 3, gross fœtal deformity 2, miscellaneous 2 The important factor here again is the unknown one In 17 cases no reason could be detected by clinical means to explain why labour came on prematurely The actual cause of death in these cases may have been cerebral hæmorrhage, atelectasis pneumonia or gastro-enteritis, but it was felt that the important predisposing factor was the prematurity

The neonatal mortality for the City of Aberdeen is 33 per 1000 and for booked cases in hospital 27 4 per 1000, but if the deaths due to infection after leaving hospital and overlying are removed the figure falls to 21 3 per 1000 Any substantial fall below this figure could only be effected by the prevention of premature labour, this problem will be discussed later

MORTALITY IN EMERGENCY CASES

During the years 1938–40 there were 187 stillbirths in 616 emergency cases—83 in full-time deliveries and 104 in premature cases In the full-time cases the most common cause of stillbirth was a mechanical factor—difficult labour and placenta prævia (41 cases or 50%) Many of the deaths in this group could have been avoided by earlier admission to hospital Pre-eclampsia in the mother, in some cases followed by accidental hæmorrhage, accounted for 24 stillbirths Some of the deaths in this group could have been avoided by better antenatal care and earlier admission to hospital with longer rest in bed There were no other groups of importance

As regards stillbirths in premature babies, the biggest factor was toxæmia in the mother (50 cases or almost 50%) The other categories were accidental hæmorrhage without toxæmia 11 cases, placenta prævia 15, cause unknown 12 In these groups fewer of the deaths are avoidable In some of the cases of toxæmia better antenatal care would have saved the child's life, but many were probably unavoidable, they include cases where the mother made a poor response to treatment, fulminating cases, and others where intra-uterine death of the fœtus occurred even where the toxæmia was apparently mild and responding well to treatment

---

[1] London 1938

[2] McNeil C *Lancet*, 1940 1, 912

There must, therefore, be a large wastage in the toxæmia group until more is known about the ætiology of eclampsia The deaths from placenta prævia are unavoidable

Of the neonatal deaths in emergency cases, 24 occurred in full-time babies The causes of death here were trauma 15, unknown 2, placenta prævia 1, infection 1, gross fœtal deformity 3, miscellaneous 2 In most of these cases of trauma the death was due to cerebral hæmorrhage following difficult labour, and without doubt some of the deaths could have been avoided if the mothers had been sent into hospital earlier in labour Deaths occurred in 55 premature babies and the causes of the premature onset of labour were unknown 10, toxæmia 8, accidental hæmorrhage 9 twin pregnancy 5, placenta prævia 8, debility 2, gross fœtal deformity 2, miscellaneous 11

DISCUSSION

Booked cases —In order to assess the wastage of child life from obstetrical causes it is convenient to consider the stillbirth and neonatal death-rates together In the Aberdeen Maternity Hospital during the years 1938–40, out of 3427 booked cases there were 187 stillbirths or neonatal deaths , this rate of 54 5 per 1000 is much less than the figure of 69 8 per 1000 for the city as a whole Discounting the Maternity Hospital booked cases, the figure for obstetric practice for the rest of the city—that is to say, domiciliary midwifery and emergency cases sent to hospital—is about 78 5 per 1000, which compares very unfavourably with the figure of 54 5 per 1000 for the hospital booked cases

Among full-time babies (95 cases) the cause of death was unknown in 25 3% of cases , trauma accounted for 18 9% infection for 18 9% and gross fœtal deformity for 8 3% A few of the deaths from trauma might be avoided The deaths from infection occurred after the children had gone home and are thus at present unavoidable, so that the main scope for improvement is in the large group where no adequate explanation exists to account for the death

Most of the premature babies (92 cases) who die succumb within 24 hours of birth because they are so feeble The cause of the premature onset of labour was unknown in 37%, toxæmia in 15 2%, debility in 13%, twin pregnancy in 8 7%, placenta prævia 7 6%, gross fœtal deformity in 5 5%, miscellaneous in 13% The more highly skilled the care bestowed on them, of course, the more chance these infants have of survival, but even with the best care many of them die Table I shows that where the child weighs more than 4½ lb at birth the chance of survival is good, but that with children under this weight the mortality rises abruptly An analysis of the neonatal deaths in premature babies in hospital shows that in a series of 89 cases, 76 were under 4½ lb and of these 59 lived less than 24 hours The problem therefore involves more than improved pædiatrics

TABLE I—RESULTS OF TREATMENT OF 352 PREMATURE BABIES IN THE ABERDEEN MATERNITY HOSPITAL, DURING 1938, 1939 AND 1940

Weight at birth (lb)	5½–5	5–4½	4½–4	4–3½	3½–3	Under 3
Infants	142	75	55	32	23	25
Deaths	7	6	22	16	14	24
Death rate per 1000	49	80	400	500	643	960

Emergency cases —As far as the analysis of the deaths in emergency cases is concerned different conclusions must be drawn Out of a total of 266 stillbirths and neonatal deaths in this group, 107 occurred in full-time babies and the biggest individual factor here was trauma (41%), followed by toxæmia 12%, accidental hæmorrhage 16%, and placenta prævia 12% Trauma, placenta prævia and toxæmia together account for 65% of the deaths and most of these could be avoided by better obstetrics A big reduction could be achieved by checking the blood-pressure regularly, avoiding the use of forceps till the head is low in the pelvis, and by sending all cases of antepartum hæmorrhage to hospital as soon as there is any bleeding

TABLE II—ANALYSIS OF 250 CASES SEEN IN SPECIALIST PRACTICE, 708 BOOKED CASES SEEN IN NURSING HOME PRACTICE AND 3427 BOOKED CASES SEEN IN HOSPITAL

Parity of mother	Full time cases		Premature cases		Pregnancies ending prematurely (%)	Death rate per 1000 births

5 and over	597	17	56	21	8 6	60
	3126	95 (30/1000)	301	92 (306/1000)		

In the 159 deaths from prematurity among emergency cases the cause of the premature labour was toxæmia 26%, accidental hæmorrhage 25% (more than half of these also had toxæmia), placenta prævia 14 5%, unknown 13 5% About a third of all the cases of premature labour were due to pre-eclampsia or pre eclampsia complicated by accidental hæmorrhage , in more than half of these the antenatal care was poor In cases of accidental hæmorrhage without toxæmia, cases of placenta prævia and cases where the cause of the onset of labour is unknown (62 cases or 39% of the total), little can be done in the present state of our knowledge

As far as the emergency cases are concerned there is great scope for improvement in both antenatal and intranatal care, which would result in the saving of many children Among booked cases only slight improvement in the infant death-rate can be looked for by improvement in treatment along the present lines The big factors are the toxæmias (the ætiology of which is understood so little), unexplained death and unexplained premature labour

Biochemical studies in metabolism would be valuable in the investigation of this problem, but we have not found it possible to undertake such investigations under present conditions We have, however, tried to find out whether there is any relationship between poverty and the high incidence of prematurity and stillbirths of unknown origin For this purpose we have compared booked cases in the maternity hospital with those of nursing-home and specialist practice Unfortunately, the numbers of the two latter groups are small and conclusions must be accepted with reserve

The figures for specialist practice (*table* II) show 3 deaths in 250 deliveries (12 per 1000) The deaths were due to anencephaly, melæna neonatorum, and cerebral hæmorrhage following spontaneous delivery There were only 5 premature labours, all due to pre-eclampsia, and no deaths among them

An analysis of nursing-home cases (table II), shows two points of interest First, there were a few deaths in full-time babies , these were mostly due to cerebral hæmorrhage following difficult labour (for example, breech presentation or forceps delivery in vertex cases) Secondly, a number of deaths occurred from prematurity, generally the result of pre-eclampsia (13 out of 18 of the infantile deaths in primiparæ) The incidence of prematurity was much greater in first than in later pregnancies , 9 6% of all babies in primiparæ were premature and only 3% in a second pregnancy. This in itself raises the fœtal death-rate in the first pregnancies, since, as the table shows, the fœtal death-rate in premature babies is much higher than in full-time babies The total infant death rate, including stillbirths and neonatal deaths, was 55 per 1000 births

Among the hospital booked cases (table II) the mortality for full-time babies was also much lower than for premature babies (30 per 1000 against 306 per 1000) In contrast to the nursing-home figures, the proportion of premature labours to the total did not fall off after the first pregnancy, and because of this the death-rate among the babies remained almost the same in each parity Whereas the main cause of fatal prematurity in nursing-home practice was pre-eclampsia, in hospital the largest group came under the heading of " cause unknown " (37% of the total)

The cause of death among full-time babies in booked hospital cases was undetermined in by far the biggest group, in contrast to the nursing-home cases or the emergency hospital cases where the commonest cause of death was trauma following difficult labour The almost complete absence of the " unexplained " factor as a cause of death in nursing-home and specialist practice and the difference in the incidence of premature labour points to the importance of economic factors, the most important of which would be deficiency in diet and lack of adequate rest among the poor Attendance at a hospital antenatal clinic and delivery under the best conditions in hospital will accomplish a great deal for these people In Aberdeen the comparative figures show that they can reduce the wastage of life due to both stillbirth and neonatal mortality from 78 5 to 54 5 per 1000 , in fact, if these figures are corrected for babies dying of infection after dismissal from hospital,* the relative figures are 81 7 and 48 4 These measures, however, cannot neutralise the effects of faulty diet and poor home conditions The figure of 12 per 1000 for specialist practice shows what can be accomplished where these adverse factors do not operate In this last group, the patients had not only good nursing and medical attention but good home conditions with the advantages of better education and sound nutrition The figures encourage the hope that when the living conditions of the poor resemble in their essential details those of the more prosperous section of the community a big saving in child life will result

The numbers presented here are far too small for any conclusions to be drawn with confidence, but they call for a similar analysis on a large scale Should the conclusions be substantiated they are doubly important in war-time when living conditions deteriorate and diet may become deficient In peace-time, first-class proteins and the protective foods were too expensive to be used in sufficient quantity by the poor Since the outbreak of war the Government, by such measures as the milk scheme, has done something to remedy this evil , but since there is a shortage of first-class proteins and protective foods diets are likely to remain deficient It is important to see that extra foodstuffs are given in the first instance to those who need them most—expectant mothers and all growing children The most efficient and economical method of doing this is by a widespread extension of communal dinners The expectant mother would thus be assured of one meal daily which would contain all the substances thought to be necessary for the wellbeing of her child She would have a much needed respite from cooking and washing-up, and there would be ample opportunity for practical education in the principles of good nutrition

SUMMARY

The causes of stillbirth and neonatal deaths in the Aberdeen Maternity Hospital have been analysed In 3427 booked cases where the baby was full-time there was no adequate explanation of the death in 25 3% of the total , trauma accounted for 18 9% and fœtal deformity for 8 3% There were few deaths from infection in hospital

Among the premature births no adequate explanation of the reason for the premature onset of labour could be found in 37% , toxæmia accounted for 15 2% The death-rate was largely determined by the degree of prematurity

The combined stillbirths and neonatal deaths in private specialist practice, in hospital practice and domiciliary practice were found to be 12 per 1000 54 5 per 1000 and 78 5 per 1000 The low figure in the first group is probably due to a combination of favourable factors—economic, nursing and medical In the second group the nursing and medical factors are favourable but economic conditions are unfavourable In the third group the high figure indicates the need for an all-round improvement in medical and nursing care as well as economic conditions

There is thus a large wastage of child life (approximately 80 per 1000 births) associated with childbirth in Scotland, intimately connected with unfavourable economic conditions, and malnutrition and fatigue in the mother If investigations on a large scale substantiate these findings, then measures to ensure proper feeding and care of pregnant women are urgently needed

RELATIONSHIP OF EXANTHEMATIC AND ENDEMIC TYPHUS

G M FINDLAY, C B E , M D , D SC EDIN

(Wellcome Bureau of Scientific Research, London)

IT has long been recognised that an attack of endemic typhus protects against infection with exanthematic typhus and vice versa, but the exact relationship between exanthematic and endemic typhus has remained obscure The usual suggestion is that endemic typhus is the more primitive form, the exanthematic typhus rickettsiæ resulting as a modification from continued passage through the human host and the human body louse (cf Castaneda 1940) There may exist intermediate strains between those that do and those that do not cause inflammation of the tunica vaginalis of the guineapig (Castaneda and Silva 1939) Earlier efforts to demonstrate an antigenic relationship in animals were however not very successful Zinsser and Castaneda (1930, 1933), Varela, Parada and Ramos (1932) and Mooser and Sparrow (1933) either completely failed to show any immunity or found only a partial immunity when guineapigs immunised with killed endemic typhus rickettsiæ were subsequently inoculated with exanthematic rickettsiæ The antigens used by all these workers were, however, comparatively weak, being prepared from the peritoneal washings of rats treated with benzol and then infected with endemic typhus Veintemillas (1939), using a more concentrated antigen prepared from irradiated rats and, giving multiple injections, protected all of his test animals against an exanthematic strain of typhus rickettsia isolated in Mexico With still richer antigens prepared from the lungs of mice and rats more striking evidence of cross-immunity between endemic and exanthematic typhus has been obtained in guineapigs

Finlayson and Grobler (1940), using a vaccine prepared in Castaneda's laboratory from an endemic typhus strain isolated in Mexico, reported that they were able to protect guineapigs against infection by both endemic and epidemic virus from South Africa A single injection of 1 c cm was sufficient to protect against endemic strains, whereas two injections of 1 c cm were required to protect against exanthematic strains Later Finlayson (1940) found that when the vaccine was concentrated to half its original volume by precipitation with alum guineapigs were protected against the exanthematic strain by a single injection of 1 c cm Analogous results have been reported by Castaneda (1941) using a murine lung vaccine from an orchitic strain L, isolated in Mexico as an antigen against the Breinl strain of exanthematic typhus Of 11 guineapigs given three injections of 1 c cm , 8 were completely protected and 3 partially protected , of 11 guineapigs given two injections the total amount per animal varying from 0 5 to 2 c cm ; 6 were protected and 5 partially protected , of 5 guineapigs given one injection of 1 c cm 2 were partially protected and 3 were unprotected It would thus seem that in guineapigs the degree of immunity bears a relationship to the amount of antigen injected The question whether a similar relationship holds good in man is uncertain

AN EXPERIMENT IN MAN

Although a considerable number of human beings have been inoculated with rickettsiæ in an effort to produce immunity against typhus very little is known about the efficacy of these various forms of vaccination The following unrehearsed experiment may therefore be worth placing on record

In January, 1940, G M F, aged 47, was given three injections of Weigl's louse vaccine containing killed exanthematic typhus rickettsiæ no reaction occurred but there was no positive Weil Felix reaction and no rickettsicidal power could be shown in the serum by the intradermal test in rabbits devised by Giroud (1938) During April, 1940, four injections of 1 c cm of a mouse lung vaccine, prepared by Durand and Giroud (1940), were given at intervals of five days, the vaccine again contained killed exanthematic typhus rickettsiæ There was no local or general reaction but subsequently the serum was shown to contain rickettsicidal immune bodies by the intradermal test in rabbits against exanthematic typhus During the next six weeks experiments were carried out on the intranasal instillation into mice of both exanthematic and endemic typhus rickettsiæ In June G M F developed a febrile reaction lasting five days with maximum temperature 101° F and for the first two days considerable frontal and postocular headache A very few discrete roseolar spots were seen on the abdomen and side of the chest On the second day of fever blood was injected into rats and guineapigs An orchitis-producing strain of typhus rickettsia was isolated There were no complications and it was possible to return to work within a fortnight

A week before G M F's illness, a laboratory technician, aged 18, had gone sick with headache and fever He had received one injection of 1 c cm of the mouse lung vaccine containing killed exanthematic typhus rickettsiæ Three days after receiving the injection he complained of slight headache with no rise in temperature and two days later was given a second injection of 1 c cm of the same mouse-lung vaccine Twenty-four hours later his morning temperature was 100 2° F He developed fever which continued for a fortnight, maximum 103 8° F, associated with headache, photophobia and a transitory rash On the third day of fever blood was injected into rats and guineapigs An orchitic strain of rickettsia was obtained from the blood

From both cases a strain of endemic typhus rickettsia was thus obtained but the disease was far more severe in the technician than in G M F The same batch of vaccine was subsequently inoculated into 12 other persons not actively engaged in typhus investigations without causing any febrile reaction, and when injected into guineapigs it also failed to produce fever In both the cases here recorded the infection was therefore contracted during work with active endemic typhus rickettsiæ, being apparently modified in the first case by the presence of some degree of immunity against exanthematic typhus, despite the fact that typhus is usually more severe over the age of 40 This unrehearsed human experiment therefore bears out the contention that there is a close antigenic similarity between rickettsiæ of exanthematic and endemic typhus

CONCLUSION

In two cases of endemic typhus infection was contracted in the laboratory In one the infection was apparently modified by previous immunisation with killed exanthematic typhus rickettsiæ, thus confirming observations in guineapigs which suggest that the relationship between the rickettsiæ of exanthematic and endemic typhus is quantitative rather than qualitative

RADIOLOGICAL VISUALISATION OF THE EUSTACHIAN TUBE

G F REES-JONES,
M R C S, D M R E
SQUADRON LEADER, R A F V R, RADIOLOGIST

JOHN E G MCGIBBON,
M B LOND, D L O
SQUADRON LEADER, R A F, AURIST

(At a Royal Air Force Hospital)

THE possibility of obtaining information by contrast radiological examination of the eustachian tube became manifest to us during the course of a clinical investigation of the conductive form of deafness which sometimes occurs during loss of altitude in aircraft Since the results have proved of practical value an account of our technique may be of use to others engaged in similar work

This type of deafness is considered to be due primarily to obstruction of the eustachian tube brought about by an inequality of the atmospheric and intratympanic pressures According to Armstrong and Heim (1937) a positive atmospheric pressure which exceeds that within the middle-ear cleft by 90 mm of mercury may bring about closure of the tube Nevertheless, in spite of the signs and symptoms, and the studies carried out by Armstrong and Heim and other observers, there is no positive proof that the aural symptoms result from blockage of the tube

For the purposes of these notes the eustachian tube may be regarded as consisting of two cones of unequal length united at their apices (fig 1) In the adult it measures 35–40 mm in length, and it forms an angle of 45° with the sagittal plane and of 30° with the horizontal plane The pharyngeal cone—cartilaginous or membranous portion—represents two-thirds of the entire length and its nasopharyngeal ostium measures 8 mm by 5 mm The tympanic cone—osseous portion—constitutes the remaining third of the tube and the dimensions of its opening into the middle ear are 5 mm by 3 mm The tubal lumen is narrowest at the junction of the apices—the isthmus—where it measures only 2 mm by 1 mm

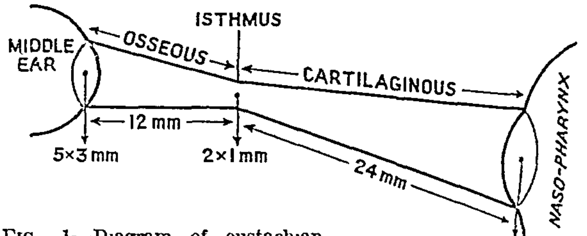

FIG 1—Diagram of eustachian tube

Published accounts of the radiological examination of the eustachian tube are few

Spielberg (1927) passed a no 4 silk catheter "about 3 cm to 4 cm within the membranous tube" through a silver catheter and then insufflated 10–15 drops of iodised oil either by a small air-pump or a soft rubber bulb He stated, also, that the eustachian tube could be filled with iodised oil through any metal tube without inserting a silk catheter If the measurements given are accurate the silk catheter was certainly in the osseous canal, if not in the middle ear Furthermore it is our experience that, although it may be possible in some cases to introduce radio opaque oil through an eustachian catheter alone, it is a haphazard method which affords incomplete pictures of the lumen of the tube

Engel (1932) demonstrated the lumen of the tube throughout its entire length in a patient suffering from suppurative infection of the peritubal cells which had ruptured into the nasopharynx While tracing the fistula from its outlet he filled the eustachian tube with opaque oil

Heimendinger (1938) took lateral and verticomental views of his patients after the passage of silk bougies impregnated with bismuth He endeavoured to inject iodised oil into the tube but was unsuccessful because the oil escaped from the nasopharyngeal orifice

Our experiments have shown that in order to obtain satisfactory radiograms it is necessary to introduce into

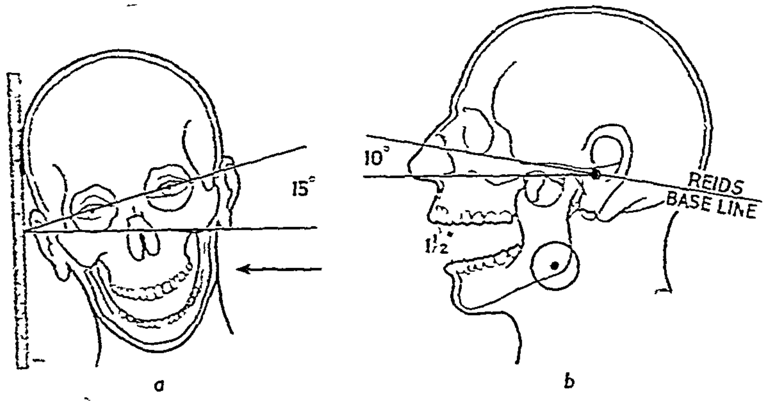

FIG 2—Positions of skull for radiography of eustachian tube

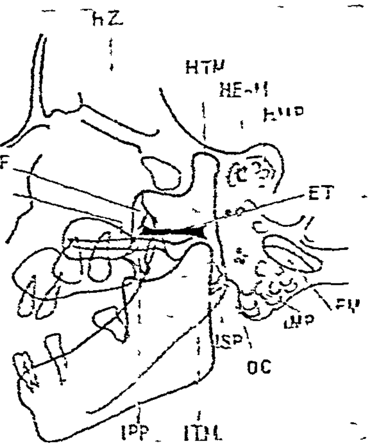

FIG 3—Relations of shadow cast by eustachian tube to surrounding bony structures H = heterolateral I = ipsolateral, Z = zygomatic arch T M. = temporomandibular articulation, E.A.M = external auditory meatus, M P. = mastoid process F.M. = foramen magnum, O C = basi-occiput S P = styloid process P P = pterygoid plate; P.M F, pterygomaxillary fissure

the tube a non-irritating opaque medium of low viscosity and as far as possible to eliminate overlying bony shadows by positioning

TECHNIQUE

Introduction of opaque medium—An eustachian catheter is passed into the orifice of the tube via a previously anæsthetised nasal fossa, and a tympanic catheter is then gently pushed through this into the lumen of the tube until it meets with an obstruction An obstruction has been present in all of the 34 cases in our series, and its site has varied from 0·5 cm to 2·5 cm from the tip of the catheter It is essential at this point to confirm the position of the catheter with a postnasal mirror, and it is surprising and instructive to note how sometimes the tympanic catheter is lying altogether outside the tubal ostium above or behind the cushion. The stilette is removed and the tympanic catheter itself withdrawn so that not more than 0·5 cm of its length is projecting into the eustachian tube, 10 minims of opaque medium is then injected into the tympanic catheter under moderate pressure from a well-fitting syringe The air contained in the tympanic catheter and the excess of opaque medium escape into the nasopharynx round the tip of the catheter Occasionally the patient feels a sharp pain in the ear for a few seconds but this is not evidence of patency of the tube since it has occurred in several cases of tubal obstruction

Opaque media—We have found iodised oils to be unsatisfactory media because their high viscosity renders their passage almost impossible through the small lumen of the tympanic catheter A 10% solution of sodium iodide afforded a satisfactory shadow, but one patient developed an acute otitis media after injection so that its use was abandoned Latterly we have employed Pyelectan which has caused no untoward symptoms and gives an adequate shadow

Position—Patients appear to be least uncomfortable in an upright posture when the catheter is in situ, and fig 2 shows the positions of the skull for radiography of the eustachian tube The head is placed in the true lateral plane with the chin tilted away from the cassette at an angle of 15° The central ray passes through the angle of the *mandible* of the opposite side to that under examination The mouth is widely opened and the head inclined backwards so that Reid's base line forms an angle of 10° with the horizontal plane Fig 3 shows the situation of the shadow cast by the eustachian tube when filled with opaque medium in relation to the surrounding bony structures when the skull is in the positions described

Exposure factors—All the films were taken at 56 kV and 40 milliampere seconds Intensifying screens were used and the radiography was carried out at a distance of 33 in

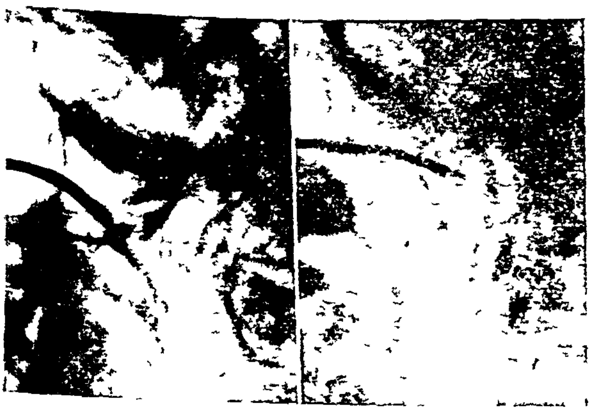

FIG 4—Typical radiograms of eustachian tube after injection of pyelectan In (*a*) cartilaginous portion of tube is filled as far as isthmus in (*b*) medium is arrested 0·5 cm from tip of catheter

RESULTS

Visualisation on the films is good as far as the isthmus. It has been impossible to make any radiological study of the osseous portion of the tube, because in all of our patients an obstruction was demonstrated in the cartilaginous segment In two cases the blockage began at the isthmus, in one at 0·5 cm from the pharyngeal orifice and in the remaining thirty-one cases at 1–2 cm. from the ostium

The shadows cast are faint in comparison with the surrounding structures so that positive reproductions give a totally inadequate representation of the definition which is actually obtained on the X-ray film For this reason only two typical radiograms are here shown (figs 4*a* and *b*)

The X-ray appearances in our series have fallen into two distinct groups When the obstruction is at or near the isthmus there is a shadow with comparatively smooth edges gently fading to a point at the junction of the cartilaginous and osseous portions This can be seen in fig 4*a* and is reproduced in fig 5*a* and *b* There is always an overflow of medium which regurgitates down the lateral wall of the pharynx and occasionally over the soft palate The most common form of obstruction occurs at 1–2 cm from the

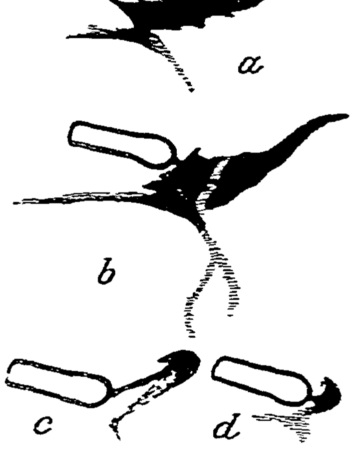

FIG 5—Tracings of typical shadows observed in cases of eustachian obstruction (*a*) and (*b*) obstruction at or near isthmus. (c) and (*d*) obstruction 1–2 cm from tip of catheter

catheter tip and in these situations pooling of the opaque medium gives rise to appearances which are typical as "mushroom-like" shadows This type is shown in fig. 4*b* and diagrammatically in fig 5*c* and *d*

SUMMARY

The technique used for contrast radiography of the eustachian tube in 34 cases of aviation "pressure" deafness is described It has not been used to elucidate any other pathological conditions of the tube, and no opinion of its use in other lesions can be expressed

Pyelectan has so far proved the most suitable opaque medium

The results show that in this type of deafness there is a definite blockage in the cartilaginous portion of the eustachian tube, but they do not reveal the extent or character of the obstruction

In two cases the stenosis began at the isthmus, in one at 0 5 cm from the pharyngeal orifice and in the remaining thirty-one cases at intermediate sites

These findings definitely dispose of the theory that there is a valve-like action of the pharyngeal orifice which, by its closure, prevents the entrance of air into the tympanum

Our thanks are due to the Commanding Officer of this hospital and to the Director General of Medical Services, R A F , for permission to publish these notes

BRACHIAL NEURITIS OCCURRING IN EPIDEMIC FORM

R WYBURN-MASON, M B CAMB , M R C P
REGISTRAR AT THE NATIONAL HOSPITAL, QUEEN SQUARE

THE occurrence of a number of cases of brachial neuritis in the outpatient department of the National Hospital and elsewhere in the last few months suggests that the condition may be the result of an epidemic infection I can find no reference to any similar condition in the literature, although of course isolated cases of brachial neuritis are well known The following 4 cases are typical of a series of 42

CASE RECORDS

CASE 1 —A house painter aged 54, admitted on Dec 2, 1940 He had suffered from a number of carbuncles in the previous 6 years In May, 1940, he developed two of these in the right axilla which after incision healed in 4–5 weeks He returned to work in June, but soon began to experience weakness in lifting his right arm above the horizontal and a severe ache in the middle of the arm, accentuated by use of the limb In the course of the next 6 weeks the pain became so severe that he had to give up work and could not sleep at night The ache spread down to the elbow along the inner side of the forearm to the wrist and up to the shoulder , it was accompanied by severe stabs of pain, "like red-hot pokers being pushed down the arm," which awakened him at night Pain ceased at the wrist but began again along the lower third of the palm as a numb, swollen sensation involving the four fingers, back and front, and originating from painful spots in the pads of the hands and fingers , most severe in the region of the point of the shoulder Any attempt to put the right hand on the back of the neck caused excruciating pain Cold numbed the fingers further and accentuated the pain , warmth might relieve or greatly exaggerate it , movement accentuated it and lying still relieved it somewhat There was no evidence that the condition was due to lead poisoning

Temperature 99° F on admission Right shoulder lower than left Right arm showed slight general wasting and very defective power in all movements, especially in those of the shoulder joint, which caused great pain Tendon reflexes brisk and equal on the two sides In the area of skin supplied by the anterior primary divisions of C3–D3, including the whole arm, considerable pain was elicited by coarse handling, with slight hypo æsthesia and hypo algesia Cold objects caused a painful response running up and down the arm like an electric shock , warmth, on the contrary, felt pleasant There was great tenderness on pressure over the brachial plexus in the supraclavicular triangle, causing violent pins and needles in the whole limb Deep sensation normal No other abnormal physical signs The cerebrospinal fluid, the blood count, and a radiogram of the cervicodorsal spine were all normal Sedimentation-rate was 3 mm (200 mm tube) in 1 hour (Westergren), urine normal At first, the severity of the pain necessitated morphia injections, Antiphlogistine poultices to the arm, diathermy to the arm and neck, and a salicylate mixture by mouth In the course of a month the pain greatly diminished The temperature became normal on the second day As the pain became less, massage was begun Power gradually returned to the limb and when the man was discharged on Feb 9, 1941, the pain was only slight and localised to an area in the region of the deltoid muscle

CASE 2 —A housewife aged 30, admitted April 25, 1941 Eight weeks before, her first child had been born after a normal labour Chloroform inhalations were used during delivery but no injections except morphia Next day she had generalised aches and pains, especially across the shoulders and in the lumbar region She could not sit up unaided and her lower limbs seemed weak and "almost paralysed" All these symptoms disappeared in 24 hours and she was well until 8 days afterwards, when a burning sensation appeared in the point of the right shoulder and deltoid muscle In the next few days this extended to the elbow, became severe and kept her awake at night, but disappeared after 3 weeks, leaving her with a dull continuous ache in the region of the wrist and elbow, shoulder and lower part of shoulder blade and right side of neck This was aggravated by movement and associated with a weakness of some movements, especially raising the arm above her head to do her hair, or stretching her arm out in front of her, which provoked sharp pain darting through the shoulder region She also experienced pins and needles in the whole of the right extremity, coming and going and leaving a numb sensation behind Since the onset she had also noticed pins and needles in all her toes, reaching at times as far as the knees and often accompanied by a sensation of heat and cold The week before admission there had been a severe ache between the shoulder blades, stiffness of the neck, an ache in the left wrist and elbow like that in the right arm, and a sensation of pins and needles in this limb extending from the fingers to the wrist Suckling her child brought on the pain severely

The right arm showed no wasting, but there was much winging of the right scapula and weakness on raising the arm from the horizontal abducted position to above the head, on abduction and forward movement of the humerus, and on extension of the elbow There was slight weakness of all other movements of the right elbow, wrist and fingers , the rhomboids, trapezius and latissimus dorsi were normal , there was slight fibrillation of the triceps The left arm showed slight weakness of all movements The right triceps jerk was brisker than the left but within normal limits All other reflexes were normal In the right arm, there was hypo æsthesia to all superficial stimuli in patchy areas roughly corresponding to the segmental area of C5 These areas were interspersed with patchy areas of hyperæsthesia and other areas the touching of which caused a sensation of pins and needles, especially in the thumb and outer three fingers In fact, the segmental area of C5 was surrounded by an area above (C4) and below (C6) where a sensation of pins and needles was evoked by pinprick Deep sensation was normal In the left arm, a similar patchy area of hyper and hypo æsthesia in the segmental area of D1 and in the tips of the inner three fingers Similar hyperæsthesia and pins and needles were evoked by pinprick in all the toes Pressure over the brachial plexus in both the supraclavicular triangles caused pain, especially on the right The right serratus magnus muscle showed partial reaction of degeneration , the electrical reactions of other muscles were normal C S F , blood-count and radiogram of spine were normal

She was treated by massage and electrical stimulation, and salicylates by mouth In a month the pain and paræsthesiæ disappeared and were replaced by hypo æsthesia Considerable improvement in power had occurred and the tendon jerks were now equal on the two sides

CASE 3 —A man aged 63, a secretary, was first seen on July 7, 1941 In October, 1940, he had noticed a severe ache starting in the back of the neck and running to the left shoulder down the outer side of the arm and forearm and dorsum of the hand The pain was worse on movement or on moving the head sideways The arm became very weak but the pain and weakness gradually improved Early in April he had suddenly found that the right foot had dropped and he was unable to raise his toes from the ground At the same time he noticed numbness in the outer side of the right calf, front of ankle and dorsum of the foot This had remained unchanged There was fairly severe weakness of all muscles of the left shoulder girdle and upper limb, proximally more than distally, and moderate wasting of all muscles All tendon jerks were absent in the left arm There was no superficial sensory loss, but considerable tenderness over the cords of the left brachial plexus and ulnar nerve There was complete paralysis of dorsiflexion of the right ankle and toes, with inversion of the foot and some wasting and fibrillation Reflexes were all normal There was complete loss of sensation to all superficial stimuli in the skin area supplied by the right external popliteal nerve Pressure over this nerve at the head of the fibula caused violent pins and needles in the area supplied by the nerve There was no tenderness over the right sciatic nerve No Lasegues sign present, the lumbar spine was mobile

CASE 4—A woman of 67, seen on July 9, 1941 Three months before she had begun to get pain in the flexors of the wrist and fingers, just below the elbow, and this gradually extended up the outer side of the right arm to the shoulder and up into the side of the neck and region of the clavicle It was of a hard, constricting nature and very severe, preventing sleep The whole arm began to feel weak A fortnight before admission it passed to the left shoulder and down the outside of the arm to the elbow and also to a small area on the ball of the thumb The pain was burning and severe This arm, also, gradually became weak On examination she had moderate weakness in all muscle groups but especially in the deltoids, right more than left, and in the muscles moving the shoulder-joint There was no wasting or fibrillation All reflexes were diminished but just present There was considerable hyperæsthesia and hyperalgesia and thermohyperæsthesia over the segmental areas of C5–6 on the right and C5 on the left, but there was slight diminution to all forms of superficial sensation over C3–D1 on both sides in the areas of the anterior primary divisions There was much tenderness on pressure over the cords of both brachial plexuses, the right more than the left

SUMMARY OF CASES

I have seen in all 42 cases of brachial neuritis between December, 1940, and August, 1941 Dr J Purdon Martin has recently seen several other cases presenting paralysis of the serratus magnus or radial-nerve lesions as their chief feature and associated with sensory changes in corresponding skin segments (thus resembling case 2), which are probably related to the condition under discussion The cases show the following age-incidence

30–39 years	6 cases	60–69 years	10 cases
40–49 "	9 "	70–79 "	8 "
50–59 "	9 "		

The youngest patient was 30 and the eldest 77 The condition was fairly evenly spread out over the whole range from 30 to 80 There were 13 cases in men and 8 in women The left side was affected in 12, the right in 8, and both sides in 3 The months of onset were June, 1940, 1 case, October, 1940, 1 case, January, 1941, 3 cases, February, 1941, 3 cases, March, 1941, 3 cases, April, 1941, 6 cases, June, 1941, 12 cases, and July, 1941, 13 cases Thus the disease appeared in the winter and persisted into spring and summer

The clinical features suggest that the anterior primary divisions of the spinal nerves from C3 to D4 inclusive, in whole or in part, are involved In most cases the upper part of the plexus, and the skin segments served by C5–6 nerves, are most affected, but on careful examination there are also, in every case, sensory changes of a wider distribution In one (case 2) there were less severe changes on the opposite side and slight sensory changes in the lower limbs In most cases the motor weakness was general and in long-standing cases accompanied by wasting, but in others it was limited chiefly to one or two muscles—e g, serratus magnus and triceps Every case began with pain, often burning, and typically situated in the region of the shoulder blade The tendon reflexes in the affected limb were usually increased or decreased, the former in earlier and less severe cases The severity varied considerably from case to case, from mild cases rapidly responding to treatment to very severe cases (case 1)

The ultimate outlook is good and in the milder cases improvement soon sets in, but the more severe cases are very refractory to treatment as far as they have been followed

The occurrence, in the winter and spring, of so many cases of what is normally a relatively rare condition, is remarkable Only 13 such cases were admitted to the National Hospital between 1924 and the present outbreak The close similarity to one another, the localisation of the lesion to the anterior primary divisions of the spinal nerves, and the tenderness in the region of the cords of the plexus and over the ulnar nerve in some cases, suggest that the condition is the result of an infection, and that the site of the lesion is in the nerves themselves at a point distal to the origin of the posterior primary divisions

RELATIONSHIP TO EXTERNAL POPLITEAL LESIONS

In the last 3 months I have also seen 7 cases of lesions occurring suddenly and for no apparent reason in the external popliteal nerve An example of this is case 5 There seems to be a relation between these cases and those of brachial neuritis, they have occurred during the same period and in case 3 the two conditions occurred at the same time

CASE 5—A cobbler aged 36, admitted on May 5, 1941 In 1938 he had a severe attack of left sided sciatica and lumbago, which cleared up after 7 weeks' rest in bed Three weeks before admission, while at work, he developed sudden left foot drop, and in a few days numbness on the outer side of the calf and dorsum of the foot On examination he had complete paralysis of dorsiflexion of ankle and toes and inversion of the foot The tendon reflexes were normal There was gross diminution of all forms of superficial sensation over the skin area supplied by the external popliteal, but no tenderness over the external popliteal or sciatic nerves A radiogram of the spine and the C S F were normal The electrical reactions of the anterior tibial group of muscles were normal

He was treated with antiphlogistine poultices, massage and electrical stimulation to affected muscles, and was given a bed boot to support the foot He improved considerably after 6 weeks' treatment

DISCUSSION

What is the nature of this condition? Is it an infection by a neurotropic virus, like herpes zoster? Is it a "fibrositic" condition? This seems unlikely, since in no case were there other rheumatic manifestations Is it an allergic reaction to some infection, like the brachial neuritis which occasionally follows serum injections? Case 2 suggests that this may possibly be so, here symptoms occurred 8 days after signs of a general infection following parturition The period of 7–14 days is a common interval before allergic manifestations appear In case 1 symptoms occurred about 5 weeks after the appearance of carbuncles One case seen by Dr Purdon Martin began with severe headache and a temperature of 104° F, and examination a few days later revealed winging of the scapula Whatever the ætiology it seems to be a clinical entity, possibly the result of an hitherto undescribed infection which is appearing in this war for the first time It may be connected with a number of cases of serratus-magnus palsy with sensory changes in corresponding skin segments and of cases of foot-drop and sensory changes in the skin area supplied by the external popliteal nerve, which have also occurred lately No light can be thrown on the source of any infection In no case did a patient frequent public air-raid shelters, there was only one case in which sore throat had preceded the illness None had had serum injections, or showed any obvious nutritional defects All my cases came from London, but in Dr Purdon Martin's cases this has not been so

SUMMARY

An unusual amount of brachial neuritis was seen in London in the eight months December, 1940–August, 1941, amounting to a small epidemic

A series of 42 such cases is reported and 4 are described in detail

The cause of the condition is unknown

I wish to thank the honorary medical staff of the National Hospital for permission to publish the case reports

RESISTANCE OF INFLUENZA VIRUS TO DRYING
AND ITS DEMONSTRATION ON DUST

DERRICK G FF EDWARD, M D LOND
(*National Institute for Medical Research*)

RECENTLY attention has been directed to the part played by dust in the spread of disease, particularly infection due to *Streptococcus pyogenes* and *Corynebacterium diphtheriæ* * Both these organisms are known to survive drying and can be recovered from the dust of rooms inhabited by infected patients (Thomas 1941, Crosbie and Wright 1941) Under experimental conditions it has been shown that by shaking and beating blankets on which streptococci have been dried the organisms can be distributed in the air on dust particles in a virulent form (Van den Ende, Lush and Edward 1940) In other infections the possibility of spread by dust obviously depends on the ability of the causal organisms to withstand drying Although influenza is regarded as an air-borne infection, little attention has been paid to transmission by dust and it has not been determined whether influenza virus can resist drying under natural atmospheric conditions, the only data collected having been in regard to its resistance to drying in vacuo in the cold It was therefore decided to investigate the possibility that dust might be a factor in the spread of influenza and to determine the resistance of the virus to drying

SURVIVAL ON DUST

Throughout this investigation the PR8 strain of influenza A virus was used Suspensions of virus were obtained by inoculating mice, their lungs were collected three days later and after being ground up were suspended in a mixture of equal parts nutrient broth and physiological saline Tests for the presence of virus were made by inoculating batches of three mice intranasally under ether anæsthesia with 0 05 c cm of the suspension under test Animals that died were examined post mortem for the presence of influenzal lung lesions Surviving mice were killed on the tenth day and examined similarly

One experiment was carried out to discover whether, after artificial impregnation of a blanket, the virus could survive and be distributed into the air by shaking A previously sterilised strip of blanket about 20 in × 8 in was heavily impregnated with a 5% suspension of virus by means of a scent spray and was then hung up to dry Five hours later it was shaken vigorously in a closed tank of about 10 c ft capacity During shaking, and for 10 min afterwards, air was sucked out of the tank through a Wells air-centrifuge at the rate of 2 c ft per minute To collect the virus 10 c cm of broth had been placed in the rotating cylinder and this was finally tested by inoculating three mice intranasally This method for recovering suspended influenza virus particles from the air was originally described by Wells and Brown (1936) The experiment was successful and moderate-sized influenzal lesions were obtained in each of the mice

On another occasion a ferret was infected with the mouse-adapted strain of PR8 in use throughout the investigation For the two or three days during which the animal was sneezing and showing the usual symptoms of infection several Petri dishes containing small amounts of sterilised dust were left exposed in various parts of the cubicle containing the ferret in its cage At the end of this time each specimen of dust was well soaked in broth to extract any virus, centrifuged gently and the supernatant tested on mice In this way virus was demonstrated in the dust from a dish placed next to the ferret cage and 3 in away from it, but not from dishes placed further away in positions which could not be reached by direct droplet projectiles

These experiments show that influenza virus can resist drying and can be demonstrated in dust that has been infected both artificially and naturally The investigation was therefore continued, to assess quantitatively the degree of survival and persistence of the virus after drying and to examine the factors that might infl these, such as physical conditions and the nature of surface on which the virus was dried

EXPERIMENTAL METHODS

As test materials for impregnation the following were used

Two in squares of cotton sheet, 1 in squares of serge, both of which had been previously well washed and then sterilised, glass microscope slides, and sterilised household dust, sieved sufficiently to remove the large fibres The squares of sheet and serge were impregnated by allowing 0 7 and 1 c c respectively of 5% influenzal mouse lung suspension to soak into them On the glass slides 0 1 c cm of the suspension was spread as a thin film along the whole of one side The dust was placed in Petri dishes and impregnated by rubbing 0 2 c cm of the suspension into it with a spatula, so that all the fluid was soaked up In each case the samples were allowed to dry by exposing them to the air of the laboratory under the ordinary atmospheric conditions prevailing They were afterwards stored in the dark in a cupboard until it was necessary to test them

The following methods were used for extracting the active virus

The squares of sheet and serge were soaked for 15 min in 5 c cm of nutrient broth in Petri dishes, the fluid being afterwards squeezed out of them as much as possible by twisting with two pairs of Spencer Wells forceps The dust was thoroughly mixed with 5 c cm of broth and the mixture centrifuged gently to recover the broth The slides were simply soaked in 5 c cm of broth In each case the broth, and tenfold dilutions of it, were inoculated intranasally into mice to estimate the amount of virus recovered

Except from the glass slides, it did not appear likely that these methods of extraction effected a complete recovery of viable virus In order to find out the proportion recovered, control samples of the materials were impregnated in the manner described and extracted at once before drying took place With the sheet there was no appreciable difference between the amount of virus recovered and that which was applied to it Only 10% of the virus applied, however, was recovered from the serge and the dust

SURVIVAL AND PERSISTENCE AFTER DRYING

Specimens of serge, sheet, dust and glass slides were impregnated in the manner described and the viable virus extracted before and after drying It was found that between 1 and 10% of virus withstood drying on the serge and the dust and 10% or more on the glass slides When squares of sheet were impregnated with 0 7 c cm of virus suspension, an amount sufficient to saturate the square almost completely, 1% of virus survived drying, but when 0 1 c cm of suspension was applied as a drop in the centre there was survival of little more than 0 01% A similar difference in survival depending on the degree of impregnation did not occur with the serge, and the reason for the difference with the sheet is not apparent In fact, the opposite effect might have been expected, if heavier impregnation had led to slower drying, for it was found that, if a square of sheet was impregnated with 0 7 c cm and drying took place slowly because of the humidity of the atmosphere, only 0 01% of virus survived

After drying, impregnated specimens were stored in the dark in the laboratory and tested for active virus after one, three and seven days, and thereafter at weekly intervals It was found that virus disappeared rather slowly at a regular rate, the length of time during which virus could be demonstrated on a substance depended on the amount initially present when drying was complete

The largest amount of dried virus was obtained on the glass slides, and the persistence of this is shown in the table In it the results of the titrations in mice are expressed numerically, and in the last column there is an estimate of the total active virus present on the slide, obtained by multiplying the reciprocal of the highest infecting dilution by 100, since the inoculum for a mouse was 1/100th part of the volume of broth used for extraction It will be seen that after three days 10% of virus remained alive and after a week 1% After five weeks virus could still be demonstrated although there was then only 0 01% of the amount originally present The rge. and they can be summarised as follows When rying was complete there was approximately 1×10^4 I D of virus on specimens of each of these materials slight decrease might or might not be detected after hree days; at the end of a week about 1×10^3 (10% of he original amount) remained alive and after two weeks $\times 10^2$ M I D (1%) This was the least amount which ould be detected and tests at three weeks were negative

---

* A review of the subject appeared in a leading article in the *Lancet* 1941, 1, 511

PERSISTENCE OF INFLUENZA VIRUS DRIED ON GLASS

Interval since impregnation	Mice inoculated with dilutions of broth extract			Estimated amount of viable virus in M I D
	1/1	1/100	1/10 000	
4 hours	5 5 5	5 5 2	2 1 0	1×10^6
24 hours	5 5 5	5 5		
3 days	5 5	3 2 2		1×10^5
7 days	5 5 5	1 1 0		1×10^4
2 weeks	5 5 5	0 0 0		1×10^3
3 weeks	3 2 1	0 0 0		1×10^2 to 10
4 weeks	2 1 1			1×10^2
5 weeks	2 1 0			1×10^2
6 weeks	0 0 0			Less than 1×10^2

Virus was extracted with broth and titrated in mice Resulting infection is expressed in terms of a numerical index Thus 5 represents death with influenzal consolidation of the lung Among survivors, killed on the tenth day, consolidation affecting three-quarters of the lung is represented by 3, half by 2 and a quarter or less by 1

Factors influencing survival and persistence of dried virus—Temperature has a considerable effect on the time for which the dried virus remains alive Squares of sheet and glass slides were impregnated with 0 1 c cm of virus suspension and dried in the usual way Half of them were kept at 37° C and half at 22° C On sheet at 22° C virus could be demonstrated on the third day and not on the seventh; at 37° C it was not detectable at the end of twenty-four hours On glass it was present in recognisable amount for four weeks at 22° C, but for less than one week at 37° C On the other hand, the higher temperature did not have the same deleterious effect during the drying process When impregnated specimens of sheet and glass were dried in the incubator at 37° C and comparison made with the amount of virus surviving drying at 22° C, it was found that on glass there was little difference and on sheet rather more virus withstood drying at 37° C This may be due to an increased rate of drying at the higher temperature leading to increased survival, on the glass the rate of drying of the thin film is probably almost maximal at 22° C

Light also had a deleterious effect on the persistence of dried virus Impregnated squares of sheet were placed in the dark as usual, and compared with similar squares kept on the bench near a window facing north In the dark virus persisted for a week, but in the light it was not detected on the third day.

In order to examine the possible effect of the amount of protein in the suspending fluid, and to mimic more closely natural secretions infected by virus, 5% suspensions of influenzal mouse lung were made in 10% horse serum broth and in normal human saliva as well as in broth-saline With each smears were made on glass slides in the usual way, allowed to dry and tested at intervals for the presence of virus The proportion of virus which survived drying and its persistence were the same for broth-saline and for serum-broth With saliva only 1% of that amount could be found after drying perhaps owing to a direct destructive action on the virus by a lysozyme-like agent such as has been described by Burnet Lush and Jackson (1939) In another experiment it was shown that reduction of the concentration of the virus by using for impregnation a 0 5% instead of a 5% suspension of lung had no effect on the proportion of virus that survived or its persistence

VIRUS DEPOSITED IN A PARTICULATE FORM

In the experiments just described impregnation was effected by wetting the test materials completely Under natural conditions, however such gross soaking with infected secretions from influenzal patients is unlikely to occur, except perhaps with handkerchiefs and from expectoration Contamination will be chiefly by droplets expelled during sneezing and coughing, and by droplet nuclei finally impinging on some surface The findings so far presented probably apply to contamination by spitting and by the larger droplets but it was considered necessary to confirm them by investigating the persistence of virus deposited as small particles or droplet nuclei It was found that when specimens of sheet were artificially impregnated with droplet nuclei 10% of the amount of virus which could be demonstrated immediately after impregnation was still alive after one week and after three weeks there was 1% On the other hand, when droplet nuclei were deposited on a smooth surface inside a closed glass bottle in one experiment no virus could be demonstrated after six hours, and in another, although virus was present after five hours, it could not be detected after twenty-four hours

DISCUSSION

It has been shown that, when certain materials are impregnated with suspensions of influenza virus, as much as 10% of the virus can withstand the process of drying and can then remain alive for days or weeks at ordinary temperatures After three days there may be little or no appreciable loss of virus, thereafter there is a steady decrease, between 1 and 10% remaining after a week. Minute dried particles containing influenza virus (droplet nuclei), such as are distributed by the coughing and sneezing of infected patients can become attached to a material like sheet and persist in a similar manner, so that 10% may still remain alive after a week These experimental results suggest that, if articles become contaminated with infective discharges from patients with influenza either directly or indirectly by means of droplets and droplet nuclei appreciable amounts of virus may survive drying and persist for at least several days In that case such articles are infective, for virus can reach a fresh host by direct contact or by the aerial transfer of dried virus on dust particles Virus has been demonstrated on dust exposed near a ferret suffering from influenza Unfortunately a similar demonstration of virus in the neighbourhood of human beings is not possible because of the low infectivity of such human strains for animals Previous epidemiological experience with influenza has not suggested that dust plays any part in its spread but further observations might be of interest in the light of these experimental findings For reasons connected with the war the experimental investigation itself has had to be interrupted

In certain other virus diseases evidence exists for believing that virus persisting in the dried state on dust and other articles may play some part in their spread Infection by psittacosis has been reported in persons handling imported feathers (see van Rooyen and Rhodes 1940) Dried epidermal scales from cases of smallpox are regarded as infective, and their aerial transfer may carry the infection to a distance With foot-and-mouth disease the results of detailed experimental investigation are available (Report 1927 1931), these show that when dried on certain materials the virus can remain alive for several weeks Hay treated with infective saliva was capable a month later of transmitting the disease to a calf which ate it Storage in the light or at 37° C had a lethal effect on the dried virus of foot-and-mouth disease, similar to that recorded here with influenza virus The time of survival of the former varied greatly according to the material impregnated. With influenza virus, however, although only a few representative test materials were employed, no such differences were noted

SUMMARY

An experiment is described showing that, after impregnation of a blanket with a suspension of influenza virus the virus survives drying under ordinary atmospheric conditions and can be distributed in the air on dust particles by shaking the blanket

Virus could be demonstrated on dry dust exposed near a ferret infected with influenza

Results are given of a quantitative estimation of the amount of influenza virus that can withstand drying on a variety of materials including household dust Between 1 and 10% was found to survive but, if drying took place slowly in a humid atmosphere, as little as 0 01% survived

The time for which the dried virus remained alive was estimated There was little depreciation after 3 days, and 10% might persist for a week and 1% for a fortnight.

Disappearance of virus was much more rapid when impregnated materials were kept at 37° C or in the light

The epidemiological significance of these findings is discussed and reference is made to other virus diseases in which a part is possibly played by dust and dried virus in the spread of infection

I am grateful to Dr M Van den Ende for helping me to finish this investigation and to Mr R E Glover for his cooperation in the experiments with ferrets

CONTINUOUS ADMINISTRATION OF ETHYL CHLORIDE

U M WESTELL, M R C S, D A
ANÆSTHETIST TO PRESTON ROYAL INFIRMARY

ETHYL CHLORIDE has been in use as a single-dose anæsthetic for over 40 years The early anæsthetists recognised its dangers, which in addition to its toxic action on cardiac muscle are mainly due to its extreme volatility, this makes control almost impossible and overdosage all too easy They regarded it as a drug whose administration required more skill and vigilance than was justified by its sphere of usefulness In 1902 Guy[1] of Edinburgh found that ethyl chloride required a smaller effective dose, and was thus rendered safer, if given in combination with nitrous oxide, and devised a simple apparatus for induction of anæsthesia by this method In 1911, Guy and Ross[2] produced another apparatus for administration of nitrous oxide and oxygen continuously, with addition of fractional doses of ethyl chloride as required This apparatus is still used in Edinburgh for dentistry Since 1911 no advance has been made, and ethyl chloride is still widely used but only in single doses

For the past 15 months I have used ethyl chloride by continuous vaporisation with nitrous oxide and oxygen The ethyl chloride was sprayed into the chloroform bottle of a Boyle or Walton apparatus in quantities varying from 5 to 20 c cm according to the anticipated duration of operation and resistance of the patient Induction was with nitrous oxide, then, if relaxation was inadequate, ethyl chloride vapour was added gradually by slowly raising the lever of the chloroform bottle (with the plunger well raised in the Boyle apparatus) When relaxation was adequate the vapour was cut down to the minimum required for maintenance Partial rebreathing was used and cyanosis avoided by adequate oxygenation Results are shown in the table By this method the anæsthesia was as easily controlled as when divinyl ether was used instead of ethyl chloride by the same technique Cough did not occur, and apnœa and laryngeal spasm, so troublesome with ethyl chloride administered alone, were rare, when they did occur they were due to too rapid increase of ethyl chloride concentration and easily stopped by cutting it down a little and adding carbon dioxide No appreciable drop in blood-pressure was noted even in patients already shocked, indeed, a sustained, mildly stimulating effect was produced in these Recovery was rapid (1–10 min, as with divinyl ether), and postoperative vomiting only very slightly commoner than with divinyl ether The period of recovery was taken as from cessation of anæsthetic to the time at which the patient could first give a coherent answer to the questions "What is your name?" and "How old are you?"

Ethyl chloride by this method is particularly useful in cases requiring frequent painful dressings where nitrous oxide is insufficient, and in these cases after-pain is notably lessened

One particular terrified refugee, aged 13, who had nine anæsthetics in her own country, was anæsthetised by this method on alternate days for 2 months No premedication was given, no after effects were seen, and the child ate a hearty meal within $\frac{1}{2}$–$\frac{3}{4}$ hr after anæsthesia on most occasions, gaining $\frac{1}{2}$ st in weight in the 2 months She had proved very resistant to ether, which caused prolonged vomiting

The quantity of ethyl chloride used varied in each case, from 3 c cm for an operation lasting 10 min in a fit adult male to 25 c cm for an operation lasting 1 hr 10 min in a similar subject, neither having had premedication The cases were mostly casualties, and a large proportion had fractures, simple or compound, lacerations of varying extent and burns The ages of the patients ranged from 4 months to 97 years Opiates were used for adults only and were either morphia gr $\frac{1}{4}$ with atropine gr 1/100, or morphia gr $\frac{1}{6}$ with hyoscine gr 1/200

The method was found to be particularly useful for ambulant casualties, who, owing to rapid recovery and absence of pain or after-effects, were able to look after themselves and go home very soon after operation, thus saving much nursing attention and couch space in a busy department It is, however, essentially a fine adjustment method, and not to be lightly undertaken by the inexperienced, to whom anæsthetics in a casualty department are too often entrusted In my view an experienced anæsthetist is especially necessary in a busy casualty department if as many cases as possible are to remain ambulant

There were 2 deaths in the ethyl-chloride series, one from septic absorption following severe burns, 6 weeks after operation, and one in an infant aged 4 months, from bronchopneumonia after laparotomy for acute intestinal obstruction, this was the only post-operative chest case in either series Four deaths occurred in the divinyl ether series, two from gas gangrene following extensive wounds, one 3 days and one 10 days after operation, and two with severe burns, one from secondary shock, 6 hours after operation and one 14 days after from toxæmia

EXPERIENCE IN 51 CASES ANÆSTHETISED WITH ETHYL CHLORIDE, GAS AND OXYGEN, AND IN 61 GIVEN DIVINYL ETHER IN PLACE OF THE ETHYL CHLORIDE

—	Duration			Incidents		Sequelæ

Opiates	3	17	9	0	2	4	0	0	1	1
Total	20	32	9	0	4	10	1	4	1	5

SUMMARY

A series of 51 cases anæsthetised with nitrous oxide, oxygen and ethyl chloride vapour are compared with a series of 61 cases in which nitrous oxide, oxygen and divinyl ether was given by the same method The ethyl chloride (3–25 c cm according to the length of operation) was sprayed into the chloroform bottle of a Boyle or Walton apparatus, and anæsthesia was maintained for periods of 10–70 min Adults received morphia and atropine or morphia and hyoscine before induction

The patients were mainly fit, ambulant casualties, but some were shocked, with extensive injuries

Postoperative sequelæ were few and transient, and constitutional disturbance minimal

Ethyl chloride seems to be brought under control by this technique, but requires the same constant watchfulness which is necessary during the administration of chloroform

THE KONDOLÉON OPERATION FOR CHRONIC LYMPHŒDEMA

E D TELFORD,
B CHIR CAMB , F R C S
ERITUS PROFESSOR OF SURGERY,
NIVERSITY OF MANCHESTER

H T SIMMONS
M D , CH M MANC , F R C S
RESEARCH FELLOW, MANCHESTER ROYAL INFIRMARY

(*Neurovascular Clinic of the Infirmary*)

IN a limb swollen by chronic lymphœdema the lesion is confined to the tissues above the deep fascia, and however large the limb may become there is never any œdema below this fascia The pathology of the condition is in the main unknown, but it is evident from the delay in the excretion of dye injected into these limbs that the normal channels of lymph return are choked Hence, surgical intervention has been directed in various and often ingenious ways towards establishing some form of alternative channel It is no doubt true that this is the only approach which promises any permanent good, since other methods, such as rest, massage and support, yield nothing but the most ephemeral improvement

In the attempt by surgery to develop alternative channels buried materials such as silk threads have been used, efforts have been made to drain the lower limb into the peritoneal cavity via the crural canal, and trial has been made of flaps of normal skin transplanted to form a bridge between the diseased area and the nearest normal tissues Such attempts have not made good , after a temporary improvement any benefit is lost by the formation of scar tissue Some continental writers have reported success after sympathectomy This, however, has not been our experience, and we have shown [1] that the operation of lumbar-cord ganglionectomy has failed to secure any permanent improvement in chronic lymphœdema

The sole method which today seems worth while is that associated with the name of Kondoleon Normally, as was first shown by Sappey there is no lymphatic communication across the deep fascia, and the object of the Kondoleon operation is to develop, by hiatus of the deep fascia, a free interchange between the diseased area and the unaffected intermuscular lymphatic channels The original conception is due to Lanz who, in a patient with lymphœdema of the thigh, cut long strips of the deep fascia, and leaving these attached by one end fixed the free ends into holes drilled in the shaft of the femur Kondoleon left the fascial strips attached by one end and plunged the free ends into the intermuscular septa, but the more recent practice has been to excise long and wide strips of the deep fascia together with a wedge-shaped area of the overlying œdematous tissue

It is, of course, likely that the success of the Kondoleon technique will, as in older operations, be hampered by the formation of deep scar tissue It is, therefore, the more necessary that the operation be not judged on its immediate effect, but only after a long period

With this object, we have recently examined 11 patients, 2 men and 9 women, on whom we have done the Kondoleon operation during the last 8 years In all these patients the operation was done for lymphœdema of the lower extremity We have excluded from this review a number of patients in whom the operation was done less than a year ago

Operation —An adequate Kondoleon operation implies a long incision stretching on the outer side of the limb from the trochanter to the external malleolus, and on the inner side from the level of the saphenous opening to the internal malleolus These incisions should be interrupted for 3 in at the level of the knee, and the inner incision will, of course, be planned to avoid the internal saphenous nerve and vein We have found it best to carry the incision at once through the deep fascia By everting the edges of the incision in the fascia it is possible easily to cut a wide strip of fascia and overlying tissue from each side of the incision The wound is closed with particular care to hæmostasis , no drain is necessary and the bandage should be firmly applied

RESULTS

If return to normal is expected of the operation, the results are disappointing In but 2 of our cases has this fortunate result been approached, and it is interesting to note that both cases were of post-traumatic origin, dating in each instance from a comparatively slight injury inflicted 6 years before the operation The end-results in the 11 patients do, however, show some gratifying features In all but 1 patient there has been no further increase in the girth of the limb, and it is pleasing to note that in no case has there been any further upward extension of the disease Many measurements of these limbs have been made under comparable conditions always in the mid-afternoon after reasonable exercise, and these show in 10 of the 11 patients a reduction in girth of ½–2 in In all, 7 patients state that they have been able to return to work and have lost the pain and discomfort which formerly rendered them incapable of sustained effort One says that ' although the leg may swell after exercise as much as before, it goes down ever so much more quickly " This statement is interesting as affording some evidence that the operation has succeeded in its object of securing a by-pass for the lymphatic flow

We think it fair to evaluate the Kondoleon operation as follows It will not secure a return to normal but it will, as a rule, reduce the girth of the limb by some 25–30% of its increase and, what is more important it appears to stop further extension of the disease It is likely to succeed in relieving the pain and discomfort of the heavy limb and may allow of a return to work For these reasons we think the operation is worth while It is safe and easy, and in the present state of our knowledge is the only operation which can hold out any prospect of improvement

SUMMARY

Eleven patients on whom the Kondoleon operation has been performed have been observed for periods of 2–8 years

The results show that the operation, although not likely to yield a complete cure, produces improvement which justifies its use for cases of chronic lymphœdema

FURTHER EXPERIENCES WITH SULPHAPYRIDINE IN FILARIASIS

K VIGORS EARLE, M D LOND & CAMB , D T M
LATELY SECOND GOVERNMENT MEDICAL OFFICER IN THE ADMINISTRATION OF NAURU, NAURU ISLAND, CENTRAL PACIFIC

SINCE the publication of a series of cases of filarial complications, successfully treated with sulphapyridine (Earle 1941a, b) some further cases have been treated and the results seem worthy of record

Lymphadenitis —The strikingly beneficial effect of sulphapyridine on the lymphadenitis complicating filariasis probably indicates that the complication is due to secondary streptococcal infection rather than to the filariasis itself No diminution in the number of microfilariæ of the blood-stream is produced by the drug

CASE 1 —A Nauruan woman aged 40 First seen on Jan 2, 1941, when she complained of fever and pain and swelling in the left popliteal space of two days duration There was a past history of several similar attacks She was a sturdy woman, with no abnormalities save enlarged tender glands of the left popliteal space The overlying skin was tense and dark red There was no enlargement of the crural, inguinal or any other lymphatic groups No septic foci were found on the left leg or foot Microfilariæ were found in the blood Local treatment produced no relief, and on Jan 6 sulphapyridine (M & B 693) was begun, being given four-hourly The first two doses were 2 g each and the remaining eleven doses were each 1 g This course was repeated The temperature fell to normal and the local pain and swelling diminished within twelve hours of beginning treatment

Cellulitis complicating elephantiasis —Devitalised elephantoid tissue is subject to recurrent secondary invasion In such conditions sulphapyridine is particularly useful, though it does not act on the elephantiasis or the underlying filariasis

CASE 2 —A Nauruan woman aged 25 First seen on Jan 6, 1941, when she complained of extreme pain and swelling of the left leg, of three days duration She was otherwise healthy except for severe elephantiasis of the left lower limb The elephantoid swelling reached up to the level of the knee

Superimposed was a severe cellulitis, extending upwards to the lower third of the thigh Microfilariæ were present in the blood at night Sulphapyridine, eleven doses (two of 2 g, the remaining nine of 1 g), was begun on Jan 6, and the course was repeated There was rapid disappearance of the cellulitis but no alteration in the appearance of the original elephantiasis

CASE 3 —*Cellulitis and filarial myositis* A Nauruan man, aged 60, first seen on Jan 4, 1941, complained of fever and pain in the right leg He was rather emaciated, with no lesions in the cardiovascular, pulmonary, alimentary or central nervous systems There was elephantiasis of both legs and the left forearm In addition, cellulitis was present in the right leg and thigh No microfilariæ were found in the blood Sulphapyridine in courses similar to those given in cases 1 and 2 produced lysis of the temperature The local inflammatory reaction subsided concurrently On Jan 14 a further swelling of the right calf was observed but this time the swelling was beneath the elephantoid tissue, in the calf muscles Sulphapyridine was again given but this time did not produce any response, even when repeated Since the pain was intolerable an incision was made and dark greenish evacuated The patient made a slow recovery

This case again illustrates the fact that, while pyridine acts rapidly on secondary infection, it is on filariasis itself The second swelling was undoubt due to a filarial myositis which is uninfluenced by sul amides In this variety of myositis the blackish pus is usually sterile (Quin 1941), thus differing from tropical pyomyositis where culture of the pus staphylococci (Hughes 1938), and in which sulphapyridine has a well-marked curative action (Earle 1939)

I wish to thank Dr B H Quin, senior Government medical officer in the administration of Nauru, for permission to publish this paper

BIATRIAL TRILOCULAR HEART
WITH ATRESIA OF THE MITRAL VALVE

E W WALLS, M D GLASG
LECTURER ON ANATOMY IN GLASGOW UNIVERSITY

Cor biatriatum triloculare with atresia of the mitral valve is seldom encountered Dudzus (1922) described a case and in his account of the specimen included a short summary of 11 published cases Since then only 2 further cases have been recorded (McIntosh 1926, Abbott 1932) In his Hunterian lectures on malformations of the heart, Keith (1909) did not include this type of congenital cardiac abnormality, but at one point, while discussing the occurrence of cor biloculare, mentioned that he had seen 3 cases in which the hearts, all from stillbirths, showed mitral atresia in association with extremely minute left atria Whether these cases were in other particulars similar to true cor biatriatum triloculare with mitral atresia is not made clear

CASE-HISTORY

The infant was admitted to hospital at the age of 11 weeks She was fairly well nourished but her colour was poor, lips and nose being cyanosed For several days she had been disinclined to feed and had been coughing a great deal During feeds she became very blue but attacks of cyanosis occurred independently of feeding, being followed by pallor The chest showed signs of considerable inflammatory congestion The heart was slightly enlarged, the sounds were pure and of good quality at the apex, but at the base only one sound could be heard, a tapping preceded by a short murmur The child became increasingly cyanosed and sunken looking and died aged 14 weeks 2 days While in hospital the heart-rate varied between 130 and 160 and the respirations between 30 and 60

The findings at autopsy confirmed the diagnosis of the chest condition but otherwise revealed nothing of note except in the heart, in which there were three chambers, two atria and one ventricle (cor biatriatum triloculare) The single ventricle, in which no trace of a septum could be found, communicated by a large tricuspid opening with the right atrium but no left atrioventricular opening was present Leading from the common ventricle was a single arterial stem, guarded by three semilunar cusps, on the dorsal wall of which was a well marked ridge This ridge represented the septum which normally divides the truncus arteriosus into aorta and pulmonary artery The pulmonary artery was here found to arise from the aorta on the right side of the septum, thus not only did this case show an undivided truncus arteriosus but the aorta and pulmonary artery as developed were transposed (fig 1) The coronary arteries were derived from a single vessel which arose from the aorta some distance above the origin of the pulmonary artery and descended to the coronary sulcus alongside the truncus arteriosus

The right atrium, which was of normal size, received the superior and inferior venæ cavæ and the coronary sinus, and communicated, as mentioned, with the common ventricle by a large tricuspid opening This opening seemed identical with a normal right atrioventricular valve The left atrium, also of normal size, received the four pulmonary veins, but no opening into the ventricle existed, there being complete atresia of the mitral valve The interatrial septum presented a patent foramen ovale, 3 mm by 1 5 mm, bounded by very clearly marked primary and secondary septa, and in addition a smaller foramen, 2 mm in diameter, situated below the fossa ovalis (fig 1) Numerous established cases of persistent ostium primum of Born were compared with this foramen but it does not appear to be an example of that condition,

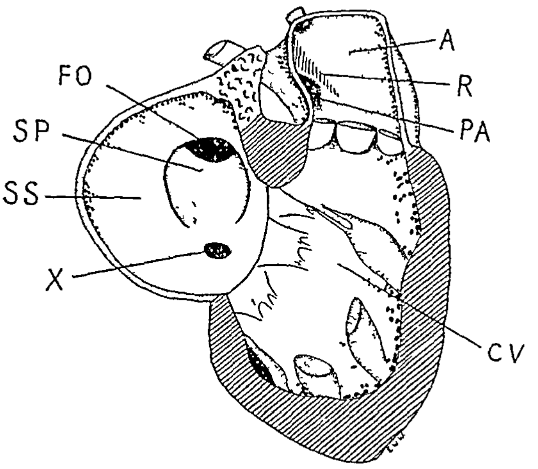

FIG 1—Heart opened from in front atrial septum shown from the right side F O = foramen ovale, S P = septum primum S S = septum secundum, X = secondary foramen, A = aorta, P A = pulmonary artery C V = common ventricle, R = ridge representing septum of truncus arteriosus

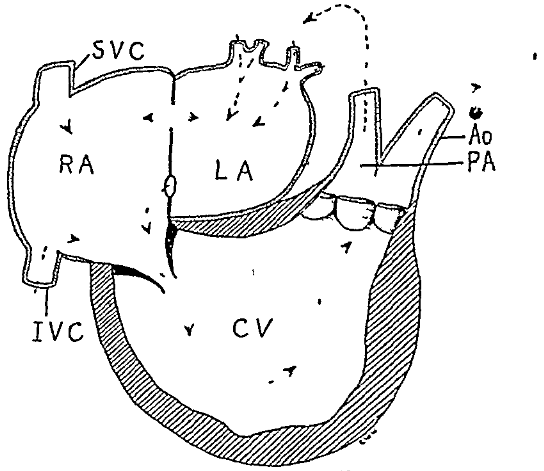

FIG 2—Presumed circulation, in the atrial septum the foramen ovale is above and the secondary foramen below S V C = superior vena cava, I V C = inferior vena cava, R A = right atrium, L A = left atrium Ao = aorta, P A = pulmonary artery C V = common ventricle

ore likely it was secondarily produced by back pressure from e left atrium owing to the mitral atresia

The circulation in this case must have been as epresented in fig 2 and that being so, survival for 3 onths is remarkable

I wish to thank Dr Mary Stevenson, in whose wards in tobhill Hospital, Glasgow, the patient was seen, and rof D M Blair for advice and criticism

Reviews of Books

sychoanalytical Method and the Doctrine of Freud

ROLAND DALBIEZ, Dr es lettres London Longmans, Green and Co Pp 515 and 331 2 vols 40*s*

To the people—many of whom are not psycho-analysts—who admire the lucidity of Freud's style it must come s a surprise that anyone should write two volumes ecause he finds Freud incapable of presenting his hought in a convincing form or of making a clear istinction between his method and his doctrine In the irst volume Dr Dalbiez presents the theory of psycho-nalysis, and in the second expresses his own views He consistently points out the relations of Freud's views o those of other workers, and his approach is partly istorical, thus he recalls the war waged by Hughlings Jackson and Head against the anatomical theories, and heir insistence on the need to think physiologically, Freud showed that we must, in addition think psychologically Contemporary theories are also contrasted with those of Freud Janet's view centred on the negative idea of deficiency, whereas Freud insisted on the positive idea of conflict, and he took up the neurological approach to hysteria at the point where Babinski left it Since he is by training a philosopher, a pupil of Meyerson whose views are outlined in a discussion on the historical and scientific methods in psychology Dr Dalbiez regards psycho analysis as a discipline not of the type of the sciences, which explain the particular by the general, but of the type which, like history, explain an event by an antecedent event He does not consider psycho-analysis to be a philosophy in itself His discussion of Pavlov's work in relation to Freudianism shows his original perspective he concludes that the conditioned reflex can be regarded as a psychological concept and as such lends support to Freudian views on psychic mechanisms and their dynamic and unconscious nature

Most critics of psycho-analysis, he considers, fail, like Freud himself, to distinguish between method and doctrine, and the whole first volume is merely preliminary to a chapter in the second volume where the associative method is thoroughly examined He holds that the method, correctly applied, can produce scientifically accurate results, but he criticises the doctrine freely, and eventually concludes that the fundamental problems of the human soul are left untouched by psycho-analysis He accepts, however, many points in the Freudian theory Thus he agrees that *infantile sexuality must* be regarded as normal, and that there is a genetic link between this and the sexopathies, but he considers that Freud has failed to make the philosophical distinction between "accidental" and "essential" Thus for the polymorphic perversion attributed by Freud to the infant Dr Dalbiez would substitute polymorphic pervertability Elsewhere he points out the difficulty of accepting the Freudian theory of dreams

In contrasting Bergson's theories of habit and memory with Freud's Dr Dalbiez suggests new paths of inquiry The part played by memory in the Freudian method would repay close attention, especially if the dynamic nature of memory was kept in mind Plenty of clinical examples drawn from various authors are quoted in the two volumes One or two assertions are based on insufficient evidence thus Dr Dalbiez accepts Peiron's claim, which would be questioned by most physiologists, that a toxic substance—hypnotoxin—can be demonstrated in the blood and cerebrospinal fluid The work, however, is a brilliant example of Gallic logic and conciseness, and the translation is worthy of them

Tropical Tips for Troops

Lieut -Colonel E T BURKE, M B Glasg, officer commanding 40th Field Ambulance, XIII Division, 1914–19 in Gallipoli, Egypt, Mesopotamia N Persia, the Caucasus and Transcaspia London W Heinemann Medical Books Pp 63 2*s* 6*d*

Colonel Burke intended this small paper-backed booklet for the use of officers and men of our armies in those regions loosely called "the tropics"—regions which embrace among others, parts of Europe, Egypt and the Near East, and South Africa, as well as the geographical tropics The text is divided into five chapters advising on tropical kit, protection against the sun, tropical diseases, vermin and mental readjustment There are one or two unexpected omissions, for example the advantages of "long shorts" and of mosquito boots are not mentioned, while the recommendation to wear a cholera-belt may not find universal acceptance In the second chapter, the malignancy of the tropical sun is perhaps overdrawn, but the chapter on tropical diseases contains much information of value to laymen Bilharzia is not mentioned, though it is surely of even greater importance to troops in the field than plague, to which a section is devoted, relapsing fever—particularly the Central African variety—and its vectors might also have found a place The chiggoe flea, too, is a minor parasite which may assume major importance in the military field, and a few words on ticks would round off the chapter on vermin The section on mental readjustment contains much wisdom This little volume should be of considerable value to those about to embark on military expeditions abroad, and it will be in large demand

Modern Dermatology and Syphilology

S WILLIAM BECKER, M D, associate professor of dermatology and syphilology in the University of Chicago, and MAXIMILLIAN E OBERMAYER, M D, assistant professor of dermatology and syphilology in the university London J B Lippincott Co Pp 871 65*s*

THIS new textbook presents many original features The paper and illustrations are excellent while the two columns of printing to a page are restful to the eye The authors give their considered opinions in lecture form, inevitably the reader will disagree with some of these opinions, but he will find them far more stimulating than a dull recital of facts References in the text are cut down to the minimum and an adequate bibliography is to be found at the end of each section Plenty of space is given to treatment—which should appeal to the practitioner, who most often consults textbooks to find out what to do No space is wasted on obsolete methods In the treatment of syphilis the recommendation that neoarsphenamine should be given every five days must be criticised The seven-day interval has proved satisfactory and it is better for patients on a long course of treatment, particularly those attending clinics, to report at the same time each week, with five-day intervals treatment will periodically fall due at the week-end, and patients will tend to default at those times

Year Book of Public Health, 1941

J. C GEIGER, M D, Dr P H., director of public health of San Francisco Chicago Year Book Publishers, London H. K. Lewis and Co Pp 544 15*s*

THIS is one of a series of year books, on various departments of medicine, founded in 1900 and since continued annually The present volume without preface or introduction, deals with recent papers on a great variety of public-health subjects, each with a footnote by the editor The matter is extracted mainly from current American publications, but due attention has been given to important contributions to British journals The selection is guided by the importance of the papers to the progress of the science and practice of preventive medicine with a bias towards those which throw light on controversial subjects or which raise new contentions It is thus a valuable guide to the progress made in the past two years Though in some places tinctured by American laws and methods, most parts of it will have equal value all over the globe Of topical interest is the chapter on military hygiene, or more correctly war-time hygiene, since in the present war problems are mainly connected with the civil population The book should have special value to British medical practitioners who are finding that war-time restrictions on imported literature make it difficult to keep abreast of recent advances in knowledge

Medical Societies

ROYAL ACADEMY OF MEDICINE IN IRELAND

At a meeting of the Section of Obstetrics on Oct 17, with Mr **Seton Pringle** in the chair, a presidential address on

Placental Infarcts

was read by Dr N M **Falkiner** He recalled the work published in 1914 by James Young, who accurately described the red infarct and drew attention to its association with eclampsia Recently workers in America, especially Bartholomew and his colleagues have revived Young's views Careful examination of placentas from all toxæmic cases have resulted in the recognition of certain types of placental infarct in association with different clinical manifestations It has been shown that placental infarcts of the more acute types are definitely associated with the toxæmias of pregnancy, and it is possible to predict the type of infarct that will be found in the placenta from the clinical history With the experience of examining placentas as "unknowns" it has been possible to establish criteria for an exact classification of placental infarcts and their relation to toxæmia Bartholomew has put forward hypotheses with regard to the significance of hypocholesterolæmia and hypothyroidism as predisposing to infarcts in the placenta Young and Bartholomew agree as to the ætiological significance of the acute placental infarct in toxæmias, but differ in their interpretation of the causal factors producing these lesions Dr Falkiner showed sections from 20 cases of toxæmia of pregnancy and demonstrated the constant occurrence of acute infarcts in pre-eclampsia and eclampsia and that the older or more chronic infarcts are associated with nephritic toxæmias

Dr **Gibbon FitzGibbon** said he had found a few infarcts, but had more or less discounted them as causative elements in the toxæmias of pregnancy

Dr **Bethel Solomons** urged that a series of placentas from normal cases should be compared with a series from toxæmia cases He asked if autopsies have been done on cases where the uterus has been removed with the placenta in situ, for these might shed new light on the decidual circulation The relation of infarcts, and a good or bad decidual circulation, to toxæmias is, he said, still an unsolved puzzle, the general belief is that when infarcts are present with good decidual circulation the toxæmia is more severe

Dr **John Cunningham** referred to the great delicacy of the vessels in the placenta, and said that the rate of growth of these vessels is enormous When growth is as rapid as this something is bound to go wrong sometimes and this to some extent explains the development of infarcts The most interesting question is whether the toxæmia is due to the infarct or the infarct due to the toxæmia He personally thought that the infarct is due to the toxæmia In cases of chronic nephritis and vascular hypertension it is not unreasonable to expect that the new blood-vessels in the placenta will be especially affected

Prof A H **Davidson** thought the chief question was does infarction come from the maternal circulation or from the fœtal circulation? He thought that it comes from the latter During his time as master of the Rotunda Hospital a number of babies born of toxæmic mothers showed albuminuria, which suggested that they had nephritis

Dr R M **Corbet** said that if, as Bartholomew and his co-workers maintain, the fœtal vessels are primarily affected, there must be a hypercholesterolæmia in the fœtal circulation the question might also be raised why the fœtus is not always affected to the same degree as the mother Dr Falkiner suggested that when the infarction is acute the whole cotyledon is involved If this is so, the toxins liberated may not be absorbed by that cotyledon, but will be carried upwards in the maternal bloodstream to the subchorionic pool where there is little absorption and thence into the general circulation, they may be taken up by the maternal tissues before blood returns to the placenta, hence leaving the f unaffected

Dr J S **Quin** thought that if these lesions are cause of the toxæmia the case of toxæmia from se accidental hæmorrhage which Dr Falkiner mentioned demand another explanation Whether the to is maternal or fœtal in origin, Dr Falkiner consid considered that both the maternal and the fœtal c tions were involved How does the separation of placenta in these cases compare with the appea of the infarcted areas in a recent infarction?

Dr W R F **Collis** had observed that in every where there was toxæmia in the mother there toxæmia in the baby as well Wherever the toxin is certainly gets into the fœtal circulation He asked w is the mechanism of the actual thrombosis Is it fœ or maternal?

In his reply Dr **Falkiner** said that this work is s going on The decidua had not been examined in any case It is very difficult to examine the decidua in the placental circulation There are reasons to back up the view that disturbance of the maternal circulation will cause infarction The greater proportion of patients who develop sugar in the urine during pregnancy develop albuminuria

---

AMERICAN UNIT AT WORK

The American Red Cross Harvard field hospital unit, planned for the investigation and treatment of infectious diseases under war-time conditions, is now at work Soon after war broke out Harvard University offered to send a field and laboratory unit to England to study epidemiological problems The offer was accepted, and in August, 1940, Prof J E Gordon of the Harvard medical school came here to confer on the details of organisation It was decided that a hospital should be included, and at the invitation of Harvard the American Red Cross agreed to provide hospital buildings and equipment and recruit nursing and administrative staff To assemble personnel and equipment and move them across the Atlantic naturally took time Now, however, a year after the development of the plan, transport of equipment and staff has been completed and the construction work is nearly done There are twenty-two buildings, connected by covered walks, each building having its own oil burning central heating system Beds are provided for 125 patients over 40% of them in single rooms, the remainder in two-bed rooms The hospital is affiliated with the Emergency Medical Service, and receives both military and civil patients One building is especially designed for admitting and discharging of patients, new arrivals are examined and in some instances treated in this building before being transferred to a bed in the main hospital Those ready to be discharged are brought back to this building for tub bath and return of clothing In other buildings are staff quarters, laboratories, operating theatre, X ray, laundry, kitchen, dining-room, store rooms, garage, offices and recreation-rooms The laboratories are well equipped for diagnostic procedures and research in infectious disease Personnel brought from America includes 60 nurses, 8 physicians, 6 laboratory technicians, 3 secretaries, a hospital superintendent, a dietitian and a chef Other employees are British The aim of the unit is to attack problems of infectious disease by mean sof field study laboratory investigation and clinical observations Field units consisting of physicians, technicians and public health nurses will be available for work in any part of Britain Cars and other equipment for mobile operations have been provided These units are being used to supplement local health organisations in times of need, and such help will be welcome now when local agencies are often reduced in staff and burdened with extra war duties So far as is practical the base will be used by the field unit for laboratory work and for supplies Actual projects in which the unit is engaged must of course depend largely on circumstances, but infections of the central nervous system and the pneumonias are special interests of members of the staff

THE LANCET

NDON SATURDAY, NOVEMBER 29, 1941

TYPHUS IMMUNISATION

HE war has now entered countries where exanthe- ic typhus is both endemic and epidemic and where uent and efficient delousing will be difficult if not ossible to carry out Typhus is endemic on the sian front from the Caucasus to Finland, although lemic proportions have not yet been reached. h of the disease described in the English news- ers as typhus is undoubtedly typhoid, which in man is known as typhus abdominalis Neverthe- there seems to be an urgent need for effective unisation if the history of the Serbian army in last war is not to be repeated On a later page be found a note on the precautions regarded by Ministry of Health as essential should infected reach this country

Unfortunately little is yet known about typhus munisation on a large scale The only vaccine ich has been in use for any considerable time is that WEIGL This is made from the intestines of lice ected with typhus rickettsiæ inoculated per rectum ree to four injections of the vaccine are necessary produce immunity while some hundreds of lice are quired for the immunisation of one person Apart m the delicate technique of rectal injection this ethod therefore requires a large staff of immunes on om the lice can be nourished It is thus hardly actical unless a whole institute is devoted solely to e manufacture of the vaccine as was done at Lwow der the direction of Professor WEIGL It is known at WEIGL remained when the Russians occupied is town in 1939 but nothing has been heard of his te and that of his institute since the beginning of the usso-German conflict The only other method of munisation used on a large scale has been the jection of living murine typhus rickettsiæ in Morocco d Tunis These rickettsiæ when living, un- oubtedly immunise against exanthematic typhus t often at the expense of an attack of murine typhus hich though not so deadly as the exanthematic rm is not to be despised The use of living murine ckettsiæ as a vaccine is also contra-indicated in untries where lice are widely distributed in the pulation, for then the stage is set for the possible nversion of murine into exanthematic typhus ckettsiæ by passage through the louse The possi- lity of using killed murine typhus rickettsiæ has en envisaged by RUIZ CASTANEDA,[1] who finds at in guineapigs multiple doses do produce some munity. On another page Dr G M FINDLAY ows from personal experience that the converse is so to some extent true, and that at any rate a rtial immunity is produced in man against murine phus by killed exanthematic typhus rickettsiæ dealing with exanthematic typhus, however seems far better to employ the killed homo- gous rickettsiæ, provided these can be obtained in fficient quantities Two methods have recently en put forward for obtaining antigenically rich vaccines of exanthematic typhus rickettsiæ Cox[2] has injected rickettsiæ into the yolk sacs of developing chick embryos while DURAND and GIROUD[3] have instilled rickettsiæ intranasally into mice From the yolk sac or the mouse lung, after treatment with formalin or phenol, vaccines may be obtained containing very large amounts of killed rickettsiæ To confer immunity, however it seems essential to give four or five injections Both these vaccines have been employed on a small scale in man but their actual value as immunising agents is at present unknown Cox's egg-yolk vaccine was employed during the recent small epidemic in Spain but the results are as yet unpublished It is known that laboratory workers who have been immunised by the egg-yolk vaccine have subsequently become infected with exanthematic typhus , in these cases of course there was probably a more intense infection and a longer exposure than is likely to occur under conditions in the field A drawback to the use of the mouse lung vaccine is obviously the possibility that other viruses present in the mouse lung may remain active in the presence of the disinfectant employed This possibility may be reduced by employing special laboratory-bred strains of mice

Before typhus immunisation is attempted on a large scale in the field certain fundamental questions must be answered—what is the minimum number of injections that produces immunity and the length of time for which immunity persists and what are the keeping properties of the vaccine ? In immunising large numbers of people it is not easy to ensure that all receive four or five injections at intervals of 5–7 days so that if possible the number of injections should be reduced to one or two In regard to the duration of immunity it is known that with Weigl s louse vaccine, as with the tick vaccine prepared against Rocky Mountain spotted fever reinoculation every year is essential Incidentally in testing immunity reliance should not be placed solely on the Weil-Felix reaction ; the agglutination test and the demonstration of rickettsicidal antibodies by the intradermal injection in rabbits as devised by GIROUD[4] should also be employed Finally there is already evidence that after 5–6 months in the ice-chest both Weigl s vaccine and the mouse-lung vaccine lose much of their antigenic power Presumably if kept at room temperatures their loss of antigenicity would be even more rapid

INDUSTRY'S CLAIM ON MEDICINE

THE months that lie immediately before us says the Minister of Labour, ' will be as crucial a period as that of the Battle of Britain,' and he has appealed to industry to increase its output by 30 or 40 per cent His appeal is a challenge to the medical profession, and in particular to those doctors who having appointments in factories can help to ensure optimum effort The question of optimum hours, Mr BEVIN has said, is not so much one of bargaining between trade-unions and employers as one demanding a scientific approach which takes account of all the factors involved at any given time and recognises the need for adjustment as those factors change Surely one scientific approach hygiene, since in the present war problems are mainly connected with the civil population The book should have special value to British medical practitioners who are finding that war-time restrictions on imported literature make it difficult to keep abreast of recent advances in knowledge

AMERICAN UNIT AT WORK

THE American Red Cross Harvard field hospital unit, planned for the investigation and treatment of infectious diseases under war-time conditions, is now at work Soon after war broke out Harvard University offered to send a field and laboratory unit to England to study epidemiological problems The offer was accepted, and in August, 1940, Prof J E Gordon of the Harvard medical school came here to confer on the details of organisation It was decided that a hospital should be included, and at the invitation of Harvard the American Red Cross agreed to provide hospital buildings and equipment and recruit nursing and administrative staff To assemble personnel and equipment and move them across the Atlantic naturally took time Now, however, a year after the development of the plan, transport of equipment and staff has been completed and the construction work is nearly done There are twenty-two buildings, connected by covered walks, each building having its own oil burning central heating system Beds are provided for 125 patients over 40% of them in single rooms, the remainder in two bed rooms The hospital is affiliated with the Emergency Medical Service, and receives both military and civil patients One building is especially designed for admitting and discharging of patients, new arrivals are examined and in some instances treated in this building before being transferred to a bed in the main hospital Those ready to be discharged are brought back to this building for tub bath and return of clothing In other buildings are staff quarters, laboratories, operating theatre, X ray, laundry, kitchen, dining-room, store rooms, garage, offices and recreation-rooms The laboratories are well equipped for diagnostic procedures and research in infectious disease Personnel brought from America includes 60 nurses, 8 physicians, 6 laboratory technicians, 3 secretaries, a hospital superintendent, a dietitian and a chef Other employees are British The aim of the unit is to attack problems of infectious disease by mean sof field study laboratory investigation and clinical observations Field units consisting of physicians, technicians and public health nurses will be available for work in any part of Britain Cars and other equipment for mobile operations have been provided These units are being used to supplement local health organisations in times of need, and such help will be welcome now when local agencies are often reduced in staff and burdened with extra war duties So far as is practical the base will be used by the field unit for laboratory work and for supplies Actual projects in which the unit is engaged must of course depend largely on circumstances, but infections of the central nervous system and the pneumonias are special interests of members of the staff xercises great care in anæsthetising the parietal oneum Intra-abdominal photography, de- ed by HORAN and EDDY,[2] is also done under anæsthesia A conscious patient is almost an itial for during the exposure the breath has to be

The main obstacle encountered at the outset that the lamp supplied with the peritoneoscope an insufficient source of light, so that a very small p with a very powerful beam had to be invented ording to present technique this lamp must be oduced through a separate peritoneal opening, a trocar is being designed which will carry h peritoneoscope and light-carrier through two locks

he value of peritoneoscopy depends on the possi- ties of extending its scope Up to now it has n useful in the differential diagnosis of liver eases, in deciding whether or not to operate in es in which secondary malignant growth is suspected d in determining the nature of pelvic tumours e parts of the abdominal cavity readily seen are e under surface and anterior border of the liver, and, by tilting the patient into the Trendelenburg position, the upper surfaces of the pelvic organs, between these two regions the intestines get in the way In obscure cases of jaundice it has been possible to diagnose with certainty cirrhosis, syphilis and secondary deposits in the liver An enlarged gall-bladder may be clearly seen, but the pancreas is not in sight Tuberculous peritonitis has been correctly diagnosed, and biopsies of the omentum and of the liver have given valuable information Fibroids and ovarian cysts are readily demonstrated The differential diagnosis of ascites can be made Early leaking of blood from an ectopic pregnancy gives an unmistakable picture The advocates of peritoneoscopy say they have been able to save unnecessary laparotomies and give material aid in arriving at a prognosis in difficult cases They do not claim that this is an infallible method of diagnosis, and in fact have found it of most aid in confirming a diagnosis already strongly suspected The question remains whether surgeons in this country will think the risk and inconvenience of an exploratory laparotomy sufficient to make them adopt this alternative

BACTERIA IN DISTILLED WATER

IT is important at any time to have reliable standards hen assessing the bacterial content of water, and in ar-time, when supplies may be contaminated, such andards need to be especially trustworthy Bigger nd Nelson[1] have cleared up some doubts about the ignificance of variations in coliform-bacillary counts, and ave called attention to fallacies in methods of filtration Though their experiments were primarily concerned with the technique of water examination, their findings have a direct bearing on everyday medicine Thus they note that water which is pure in other respects may acquire from rubber tubing, corks or filters traces of powdered talc, asbestos, silica or other earthy matters, and though these may be sterile and protein-free their presence makes it possible for bacteria to grow in the water as soon as it comes into contact with air These solids do not form the nourishment of the organisms, which live, it seems, on carbon dioxide, traces of ammonia and perhaps other minor gaseous constituents of air The action of the siliceous particles appears to be catalytic, in their presence distilled water—which normally will not permit contaminating coliform bacilli to multiply—becomes strongly favourable to their growth This finding throws light on the work of Knott and Leibel,[2] who reviewed the factors inducing pyrogenic properties in resh and stored distilled waters used to prepare solutions or intravenous injection Their experience suggested that a reaction in the patient was more likely to be provoked by traces of protein (often bacterial in origin and detectable by a rise in albuminoid ammonia) than by particulate or inorganic matter Yet they remarked that it was a commonplace of the preparation room that solutions showing inorganic deposits were very liable to prove pyrogenic, and if such reactions were to be avoided deposits of any kind were inadmissible The work of Bigger and Nelson seems to bring these apparently conflicting experiences into line In the absence of siliceous matter, bacterial contamination of doubly distilled water is not followed by growth of organisms, but if sufficient particles of silicate are present multiplication begins even at room temperature Both factors are thus necessary, but neither the initial contamination nor the number of particles present need be large for organisms to grow Thus small lapses from technical perfection may produce serious and far-reaching pyrogenic results No special silicate and no particular contaminating organism can be held responsible, Bigger and Nelson produced the same results with various silicates and with most of the common coliform organisms and their variants It is thus unnecessary to postulate a special strain of "distilled water bacillus," as once was the fashion, or to blame a particular bit of the customary apparatus Those charged with the preparation and care of intravenous supplies must beware of traces of catalytic silicate and of the chance coliform contaminant

CATGUT SUTURES

CATGUT has been employed for the ligature of vessels since the time of Galen, it was not until last century that it came into use as a suture material Since then it has been almost universally adopted, for its qualities conform closely to those of the ideal suture, but it has to be used with discrimination Howes[1] points out that catgut is a foreign body and excites a tissue reaction which is sometimes accompanied by infection, particularly when it is used in the skin and mucous membranes Apparently catgut encourages infection by acting as a culture medium It is also not well tolerated by muscle and in fat, where the poor blood-supply is probably responsible for a low-grade inflammatory reaction with considerable necrosis and induration To minimise the risk of infection and the foreign-body tissue reaction, Howes advocates the employment of catgut in fine sizes arguing that in any case the strength of a sutured wound is limited by the power of the tissues to retain the suture The tensile strength of chromic catgut no 1 is about ten times that of aponeurotic tissue To employ such a size is clearly unnecessary, although allowance must be made for the weakening of the thread from absorption, its tensile strength being probably reduced by half four days after insertion Howes suggests that no size greater than no 0 is needed in suturing any tissue and that much finer gauges (0000 or even 00000) should be used in tissues which have a poor holding power for catgut If additional strength seems necessary he advises a larger number of interrupted sutures, although he points out that there is no advantage to be gained by placing them closer together than 1 cm Bowen[2] says that larger must be that of medicine as a whole, the combined wisdom of all who have the privilege of supervising the health of the workers The effects of abnormal hours on health are known , they have just been set out [1] again with authority by a select committee, but we need more observations on the effects of different work spells Admittedly, excessive overtime for a long period has a devastating effect on the human reserve of strength, both physical and mental Over short spells of a month or two, or even three as after Dunkirk, effort can be greatly intensified without collapse But over six months, the precise period mentioned by Mr BEVIN, it would be folly to drive factory workers blindly, without regard to rest and recreation Production is by no means directly proportional to the number of hours worked , the optimum hours for regular output are far less than those which can be maintained in a spurt The problem with which we are faced is to find the correct work spell for each group of workers, for each gang, for each process, for each department, and for each firm Fatigue, that scientifically vague yet expressive word used to sum up the results of overwork, can at present only be measured in terms of output , if fatigue appears in the individual, in the squad, in the gang, in the shop, then production falls And because fatigue is cumulative it follows that the national effort must decline if the rules so truly laid down by the Health of Munition Workers Committee in the last war, and amply confirmed by later experience, are not applied by those in authority

How is this to be done ? The first step is to apply existing knowledge and this is now, we are assured, the firm intention of the Government as stated in the report mentioned above and summarised last week in these columns (p 648) No longer is the accumulated wisdom of the Industrial Health Research Board and its forerunners in regard to the relation of working hours to output, tested again and again and proved right every time, to be set aside by the producing departments Patriotism is not enough , we can be ruthless with materials but not with the human tools that fashion them To ensure the perfect adaptation of workers to their work would no doubt require an industrial medical service with a code and practice as elaborate as (say) that of the school medical service But, as the B M A report [2] published today insists, an adequate medical service does not necessarily involve an elaborate and expensive organisation Last year's order of the Ministry of Labour paved the way by giving the Factory Inspectorate discretion to introduce doctors, nurses and welfare officers into any factory engaged on armament work There should be, says this report, in *every* factory, large or small, arrangements for the medical supervision of the workers Before the war there were in this country some 520 factories employing a thousand or more workpeople, and 137,000 employing less than 250 It should be possible for a group of smaller firms to cooperate in appointing a medical officer who will spend his whole time in industrial medical work , and there is much to be said for having some advisory body to help the employer get the kind of medical officer who can safely be given a free hand when appointed The proper placing of workers a to their fitness, their continued supervision working conditions after return from illness, of the occupational hazards and the best way to them, a careful watch on the beginnings of neuroses—these form the background of a job might well become as attractive as that of the school famulus And to become this the medical officer must be left to develop his style hindered, with direct access to the management he needs it The Association of Industrial M Officers has also devised a training scheme which regards as practicable even in war-time, by w special university committees, including doc employers and trade-union officials shall ar courses in industrial medicine and obtain facilities entry into all kinds of factories Actually the int of the general practitioner in the subject is be much quickened these days and there is a good prospect, if the war goes on long enough, of the doctor regaining the intimate knowledge of his patients daily lives that he lost when they entered the erstwhile gloomy portals of the factory This new awareness will provide the clue to the " research " which is regarded as something apart and out of the question at present Its essential basis will be what industrial life looks like to doctors who move freely within it

PHOTOGRAPHY THROUGH THE PERITONEOSCOPE

As early as 1901 the abdominal viscera of a dog were seen through a cystoscope introduced into a pneumoperitoneum Since then the peritoneoscope has been much improved, and the latest triumph is the perfection of a method of colour photography which makes it possible to attach a coloured picture of his abdominal organs to the patient's clinical notes Yet the enthusiasts for peritoneoscopy are still few, and there seem to be three reasons for this lack of favour the procedure may be accounted unsafe , its scope may be too limited , or the alternative (usually exploratory laparotomy) may be considered so much more satisfactory that any added risk is considered worth while From published accounts the dangers of peritoneoscopy do not seem alarming GARREY [1] has reported 75 peritoneoscopies without a complication, except for slight sepsis in the abdominal wall of one case His patients were, on an average, 36 hours in hospital He discusses the experience of other observers, notably of RUDDOCK, who has completed 1500 examinations, and concludes that peritoneoscopy has only a fraction of the mortality of laparotomy, while it saves money and hospital beds The first part of the operation is the induction of a pneumoperitoneum An area in the midline of the abdominal wall about 5 cm across, just below the umbilicus, is anæsthetised by procaine infiltration An incision 1 5 cm long is made through the skin, and a small blunt trocar and cannula are inserted through which the pneumoperitoneum is induced The larger cannula which is to act as the sheath for the optical instrument is introduced through a nick in the anterior fascia GARREY gives as the essentials for the patient's comfort during the procedure gentleness in all movements—no jolting and no touching of visceral surfaces by the instrument He ion must be the means by which society perpetu-is typical patterns the means by which it forms a l circuit and precludes criticism of its basic assump-n, and one of these assumptions is the validity of stitution of war as a means of settling differences een states No scientific view of war says he, can rmine our conviction of being morally justified we fight against wrongful aggression, just as we need doubt our moral right to defend ourselves or our biding neighbours against robbery with violence though a detailed analysis may convince us that established institutions are responsible for producing inals In a now forgotten book "The Science of er" Benjamin Kidd showed how our social institu-s depended upon a social heredity. and although le through the centuries are capable of rapid and cal change which can be consciously directed. Mr ding indicates means by which our social heredity d be altered towards integration An international ority to enforce peace, he points out is domination the grand scale He would have us recognise that inant behaviour is an institution which our culture devised and perpetuated just as the neurotic person created his incapacitating illness Prophylaxis must end on psychological security for the individual elimination of those family and social traditions ch preclude criticism of society s basic assumptions first requirement could partially be met by ological changes. the second, he thinks, calls for widespread application of individual analysis, parti-arly of child analysis. The proposition thus to alter social life is alarming he admits, our impulse is to se a firmer clutch on what we already have, even ough what we already have includes war A similar action of insecurity to any invitation to change even small matters, stands in the way of all integrative haviour

This summary of his views cannot do justice to the lance of the book, or to its careful study of the mental ocesses involved in the warlike spirit To follow the thor all the way, however, would call for a detachment hich few of us can achieve in these times though perhaps e Chinese could approach it Their custom of allowing defeated enemy to save his face is fundamentally sound, oted in common sense But to put down Mr Harding s ok and pick up a daily paper is to pass into another orld not to be measured by his standards and values ll the more satisfying is it that such a work can be blished at this stage Whether the author s conclu-ons are right or wrong the mood in which he handles is the most pressing problem mankind has ever faced, the only one reaching towards a solution.

FUNCTION OF THE TRIGONAL MUSCLE

The trigonal muscle of the human bladder is made up two parts—Mercier s bar and Bell s muscles Macleod[1] considering their function correlates their hypertrophy th various pathological findings The principal actions of the muscle as a whole in relation to micturi-n appear to be to straighten out and eliminate the ethral angulation to form a smooth channel leading ards and into the urethra, and to maintain this ooth passage way, especially towards the end of cturition The two parts of the muscle according Macleod, become hypertrophied under different cumstances—the interureteric bar, when there is tra vesical obstruction, such as a urethral stricture d Bell s muscles in the presence of a prostatic projec-n or a stenosis of the bladder neck The hypertrophy Bell's muscles in such conditions is explained by the t that they have increased work to do to provide a ooth gully along which the urine may run Macleod s dings are derived from cystoscopic examinations and post-mortem observations The observation that the interureteric bar is thickened in cases of extra-vesical obstruction has a special interest since it runs counter to the opinion of Frontz and Landes who hold that the bar is not thickened in cases of urethral stricture Macleod also throws light on the working of the trigonal muscle According to him the interureteric bar prevents encroachment of the bladder mucosa on the smooth surface of the muscle when the bladder is nearly empty

EXPECTORANTS

At this time of the year shrouded in November fog our island home becomes once again a land flowing with ipecac and ammon carb The use of expectorants to increase and liquefy the sputum is firmly established by tradition, and the futility of medical treatment—as distinct from skilled nursing—in the management of exacerbations of chronic bronchitis is probably the main reason for the routine prescribing of these drugs. it is not that they have been proved to be of value but that they are as good a placebo as anything else The physio-logical basis for the use of expectorants is perfectly sound the output of secretion from the bronchial mucosa can be increased by vagal stimulation, and the same effect can be produced reflexly by irritating the vagus endings in the stomach mechanically or by means of drugs It is well known that nausea and vomiting due to gastric irritation are accompanied by increased bronchial and salivary secretion and not infrequently a cold sweat provides additional evidence that the enhanced activity of the cholinergic fibres has spread far afield in the vegetative nervous system But no convincing evidence has yet been produced to show that these physiological observations can be usefully applied in therapeutics The only exception to this is that emetics are occasionally administered to children suffering from acute bronchitis in order to promote transient bron-chorrœa with the object of flushing viscid secretion from the respiratory tract Few indeed are the patients with chronic bronchitis who would submit frequently to the depressing experience of parting with their gastric contents in exchange for the fleeting and sickly pleasures of profuse expectoration Nevertheless, it was probably the efficacy of this form of treatment in children which led to the unjustifiable assumption that subemetic and even subnauseating doses of drugs of the ipecacuanha series would produce the same effects on the bronchial secretion as emetic doses It is remarkable that so little attention has been paid to the time of administration of expectorants in relation to meals Only a small minority of people experience nausea when they take average therapeutic doses of these drugs on an empty stomach, and it therefore seems highly improbable that such doses can excite reflex effects by stimulating the gastric mucosa when the interior of the stomach is protected by food-stuffs and the mucoprotein of the gastric juice By clinical observations on patients suffering from chronic bronchitis Alstead[1] has shown that no significant change occurs in the output of sputum when patients receive maximum therapeutic doses of the expectorants in common use Perry and Boyd[2] by experiments on rabbits and cats, have confirmed Alstead s findings in so far as it is possible to apply to man observations made on animals Using a dose of ammonium chloride corresponding on a body-weight basis to that of Alstead, they could detect no increased output of respiratory-tract fluid This is particularly interesting in view of the substantial dosage of ammonium chloride which Alstead s patients received—gr 80 daily The rest of the paper by Perry and Boyd will make a stronger appeal to the pure experimentalist than to the practising doctor, for the doses of the drugs under investigation were so large that the results cannot be applied to man Thus an sizes of catgut are actually digested more rapidly and lose their thread strength earlier than finer ones, because of the greater tissue reaction produced by the larger sizes and the more certain impregnation of the smaller gauges of chromic catgut during manufacture Howes maintains that the incidence of wound infection is reduced and healing hastened by paying attention to these points These views are supported by previous experimental work Bates[3] points out that the edges of a healthy wound do not adhere firmly for the first four days but thereafter the strength of the junction rapidly increases until by the tenth day it approaches normal The ideal suture must therefore retain its strength during the first ten days of healing Bates's experimental studies showed that the finer sizes of chromic catgut (000) retained an adequate tensile strength for a fortnight, and that healing was rapid when they were used, whereas larger sizes (3) had little to do after a week, although the wounds were poorly healed even at this stage Plain catgut of all sizes was even more rapidly absorbed and accompanied by inflammatory reaction and delayed healing Bower, Burns and Mengle,[4] from experimental work on dogs, reached similar conclusions regarding the healing of intestinal wounds and laparotomy incisions They have applied their experimental findings clinically with success Unabsorbable suture materials have been growing in popularity in recent years, particularly in America Those who advocate their use have emphasised the disadvantages of catgut Whipple[5] points out that among the factors influencing wound healing the use of fine needles and sutures is important, in order to avoid trauma and foreign-body tissue reaction He therefore advocates the employment of silk, but it seems that when catgut is used in suitable sizes most of the objections to it disappear

VAGINAL EXAMINATION DURING LABOUR

So much has been written about the potential dangers of making a vaginal examination during labour that in the ranks of the extremely cautious this procedure has been totally vetoed and replaced by the routine employment of the rectal route for diagnosis and prognosis A vaginal examination in labour undoubtedly carries with it a small but ever present risk of introducing infection from the perinæum and the lower reaches of the vagina into the cervix and uterus or further, such an infection may be endogenous from the patient herself or exogenous from the examiner's hand or person, especially his nasopharynx Whatever precautions are taken there still remains a small risk Such precautions include the intelligent use of an impervious mask to cover mouth and nostrils, the exclusion from the labour ward of all personnel harbouring any form of nasopharyngeal infection, however mild, not forgetting the common cold and the seasonal sore throat, the employment of complete surgical asepsis for the examining hand and the use of a dry sterilised glove, careful toilet of the area of examination, and the generous exhibition of some reliable antiseptic, such as Dettol cream If all these precautions are faithfully observed we have at least given as few hostages to fortune as we can But the determining factor is not only the method but still more the number of examinations One or two vaginal examinations carry but a small risk, but every repetition increases the danger, especially if the repetition involves a number of different people, such as the outside practitioner, the admitting midwife, the pupil midwife or medical student, the resident house surgeon and perhaps as a final court of appeal the consultant These multiple vaginal examinations constitute a real danger and should always be discouraged, since universally accepted figures show that the morbidity-rate rises in direct proportion to the number of antepartum examinations, and m a contra indication to cæsarean section sh ultimately advisable

On the other hand there is no doubt that examination is the only certain method of assessing the degree of dilatation of the os in cases—for example, when the presenting part is by a thin membrane of undilated cervix and dilatation is diagnosed on rectal examination It the only accurate way of diagnosing the p when this is masked by œdema of the pr and the rectal findings are equivocal The supporters of the rectal route claim that as information can be obtained by this as by examination, but they admit that practice and are essential, and they are mostly prepared to vaginal examination when in difficulty or doubt dangers of the rectal approach are that it leads to of false security and therefore too frequent by too many different people on any one case and antiseptics are apt to be neglected and the method of examining the rectum readily haphazard, thus the inadequately sterilised thumb be placed on the introitus Erving and Meister[1] whether a finger in the rectum which rubs the dirty posterior vaginal wall into the cervix and presenting part is any less risky than a properly carefully performed vaginal examination They port the limited use of the vaginal route with convincing figures In 1000 cases consecutively delivered in the maternity unit of the Millard Fillmore H Buffalo, 97 5% of whom were examined vaginally average of 1 4 times, there were no maternal deaths, the corrected fœtal mortality was 2 7%, 4 5% of mothers were febrile according to the League of standard In extenuation of even this small mor rate, it must be noted that Erving and Meis cases were largely complicated and 75% were deliv operatively, a fact which in itself accounts any sepsis The conclusion to be drawn is that carefully conducted vaginal examination, done once twice only, is no more dangerous than a rectal exa nation, while its diagnostic exactitude renders it gre preferable

WHY DO MEN MAKE WAR?

War, says Mr D W Harding in "The Impulse Dominate" (London Allen and Unwin Pp 25 *7s 6d*) is a social institution, sanctioned alike by the aggressor nations and ourselves During the periods between wars the ordinary citizen has no for war, but he has acquiesced in the principle domination or submission as the rule in private life confronted with dominant intentions on the other (as the citizens on both sides feel sure they are) he see nothing for it but resistance Now come in kinds of exacerbating influences innate impulses, propaganda, and rumour—directed spontaneous—aided by that process of rational which leads even the most intelligent to ma reasons for their emotional responses, and by citizen's dim understanding of international a The author notes the view that psychological th belittles efforts to exclude war, but he maintains the human nature we know is institutionalised nature, not the biological product that an reading of psycho-analysis would suggest If the p analytic view is correct it means that the emotio leading to war are "neurotic," for the greater influence of repressed impulses in determining behav the more neurotic it is

Mr Harding seems to put his finger on the p knot in this tangle when he writes "The early f on must be the means by which society perpetu- s typical patterns, the means by which it forms a circuit and precludes criticism of its basic assump- ', and one of these assumptions is the validity of stitution of war as a means of settling differences en states No scientific view of war, says he, can mine our conviction of being morally justified we fight against wrongful aggression, just as we need loubt our moral right to defend ourselves or our biding neighbours against robbery with violence though a detailed analysis may convince us that stablished institutions are responsible for producing mals In a now forgotten book "The Science of er" Benjamin Kidd showed how our social institu- depended upon a social heredity, and although le through the centuries are capable of rapid and al change which can be consciously directed Mr ding indicates means by which our social heredity d be altered towards integration An international iority to enforce peace, he points out, is domination he grand scale He would have us recognise that inant behaviour is an institution which our culture devised and perpetuated just as the neurotic person created his incapacitating illness Prophylaxis must end on psychological security for the individual elimination of those family and social traditions ch preclude criticism of society's basic assumptions first requirement could partially be met by ological changes, the second, he thinks, calls for idespread application of individual analysis, parti- arly of child analysis The proposition thus to alter social life is alarming, he admits, our impulse is to e a firmer clutch on what we already have, even ough what we already have includes war A similar action of insecurity to any invitation to change, even small matters, stands in the way of all integrative haviour

VAGINAL EXAMINATION DURING LABOUR

So much has been written about the potential dangers of making a vaginal examination during labour that in the ranks of the extremely cautious this procedure has been totally vetoed and replaced by the routine employment of the rectal route for diagnosis and prognosis A vaginal examination in labour undoubtedly carries with it a small but ever present risk of introducing infection from the perinæum and the lower reaches of the vagina into the cervix and uterus or further, such an infection may be endogenous from the patient herself or exogenous from the examiner's hand or person, especially his nasopharynx Whatever precautions are taken there still remains a small risk Such precautions include the intelligent use of an impervious mask to cover mouth and nostrils, the exclusion from the labour ward of all personnel harbouring any form of nasopharyngeal infection, however mild, not forgetting the common cold and the seasonal sore throat, the employment of complete surgical asepsis for the examining hand and the use of a dry sterilised glove, careful toilet of the area of examination, and the generous exhibition of some reliable antiseptic, such as Dettol cream If all these precautions are faithfully observed we have at least given as few hostages to fortune as we can But the determining factor is not only the method but still more the number of examinations One or two vaginal examinations carry but a small risk, but every repetition increases the danger, especially if the repetition involves a number of different people, such as the outside practitioner, the admitting midwife, the pupil midwife or medical student, the resident house surgeon and perhaps as a final court of appeal the consultant These multiple vaginal examinations constitute a real danger and should always be discouraged, since universally accepted figures show that the morbidity-rate rises in direct proportion to the number of antepartum examinations, and a contra-indication to cæsarean section sh ultimately advisable

On the other hand, there is no doubt that examination is the only certain method of assessing the degree of dilatation of the os in cases—for example, when the presenting part is by a thin membrane of undilated cervix and dilatation is diagnosed on rectal examination It the only accurate way of diagnosing the pre when this is masked by œdema of the p and the rectal findings are equivocal The supporters of the rectal route claim that as information can be obtained by this as by examination, but they admit that practice and are essential, and they are mostly prepared to vaginal examination when in difficulty or doubt dangers of the rectal approach are that it leads to of false security and therefore too frequent by too many different people on any one case and antiseptics are apt to be neglected and the method of examining the rectum readily haphazard, thus the inadequately sterilised thumb be placed on the introitus Erving and Meister[1] whether a finger in the rectum which rubs the dirty posterior vaginal wall into the cervix and presenting part is any less risky than a properly carefully performed vaginal examination They port the limited use of the vaginal route with convincing figures In 1000 cases consecutively delivered in the maternity unit of the Millard Fillmore H Buffalo, 97 5% of whom were examined vaginally average of 1 4 times, there were no maternal deaths, the corrected fœtal mortality was 2 7%, 4 5% of mothers were febrile according to the League of Na standard In extenuation of even this small mo rate, it must be noted that Erving and Me cases were largely complicated and 75% were deliv operatively, a fact which in itself accounts any sepsis The conclusion to be drawn is that carefully conducted vaginal examination, done once twice only, is no more dangerous than a rectal exam nation, while its diagnostic exactitude renders it grea preferable

WHY DO MEN MAKE WAR?

WAR, says Mr D W Harding in "The Impulse Dominate" (London Allen and Unwin Pp 256 7*s* 6*d*) is a social institution, sanctioned alike by aggressor nations and ourselves During the periods between wars the ordinary citizen has no for war, but he has acquiesced in the principle domination or submission as the rule in private life confronted with dominant intentions on the other (as the citizens on both sides feel sure they are) he c see nothing for it but resistance Now come in kinds of exacerbating influences innate impulses, propaganda, and rumour—directed spontaneous—aided by that process of ration which leads even the most intelligent to reasons for their emotional responses, and by citizen's dim understanding of international a The author notes the view that psychological t belittles efforts to exclude war, but he maintains the human nature we know is institutionalised h nature, not the biological product that an reading of psycho analysis would suggest If the p analytic view is correct it means that the emo leading to war are "neurotic," for the greater influence of repressed impulses in determining beh the more neurotic it is

Mr Harding seems to put his finger on the p knot in this tangle when he writes "The early f

GENERAL MEDICAL COUNCIL

PRESIDENTIAL ADDRESS

NING on Tuesday the 154th session of the council L EASON began with a word of regret that they not sit in their own home as he had hoped in May again therefore the council was availing itself of enerous hospitality of the Royal Institute of British tects He recalled the death since last session of Robert Briggs Wild, who represented Manchester ersity on the council 1922–27 The pharmacopœia mittee had greatly benefited by his special knowledge experience in pharmacology and therapeutics ingham University had chosen its medical dean, L G Parsons, to fill the place vacated by Mr gee after fifteen years of varied service on the examon, executive and curriculum committees which all profited by his terse and pointed observations also welcomed Dr Thomas Fraser, lately president he British Medical Association, elected in May to fill place of Sir Norman Walker as direct representative Scotland, and Prof W J Wilson, medical dean Queen's University Belfast, as successor to Professor ry, now sitting on the council as a Crown nominee

DEFENCE REGULATION 32B

r Eason pointed out how this regulation debarred ctor from temporary registration unless he could show t he was by law entitled to practise in some territory part of it) outside the United Kingdom to which the ulation had been applied The Order in Council laid vn that an applicant must show to the satisfaction the council "that he holds a medical diploma or lomas," and after consultation with representatives the Home Office, Department of Health for Scotland, d British Medical Association, the regulation was nended, in September by adding after "holds" the ords "or is duly qualified to obtain"

Effective applications for temporary registration could herefore now be made by persons who are by law ntitled to practise in any place outside the British Islands, or, though not so entitled, hold (or have held) a medical diploma granted in any such place, or have passed examinations qualifying for it

The new order, Mr Eason remarked also extends acilities for entry into civil practice by deletion of the vords "not involving medical attendance on patients n their own homes" Applicants may now enter employment as assistants to practitioners whose names ppear (other than temporarily) in any of the three ections of the Medical Register These amendments, he aid, will greatly relieve the responsibility in deciding difficult and doubtful cases, at the same time greatly ncreasing the responsibility for securing a guarantee hat every applicant has the requisite knowledge and kill for the efficient practice of medicine, surgery and midwifery Happily in these matters he had been able o rely upon the experience and information of the onjoint Examining Board

THE MEDICAL STUDENT'S SCIENTIFIC GROUNDING

The council will have noticed, said the President, the evival of interest both in the medical and in the lay ress in the preliminary and early scientific education f the intending medical practitioner No doubt the ducation committee would take these comments, riticisms, and suggestions into careful consideration, hough the problems raised were carefully considered y the curriculum committee and the council before the 930 resolutions on professional education which came nto operation in November, 1938 Every medical student should, he said, have a thorough general education s well as the grounding in the basic sciences without which he cannot expect to profit by his later professional tudies The difficulty is that a complete general education would make a medical training so long as to be lmost impracticable for the average student to spend the ime or afford the cost Some compromise between xtreme views was therefore essential, although it might ail to satisfy those whose interest was concentrated upon a particular part of the curriculum

FLOWERING OF A HEALTH SERVICE

HEALTH AND MEDICINE IN THE U S S R

Virchow, in the last century, said "Medicine is a social system" With this as his text Dr A W Lipmann-Kessel, speaking at Aylesbury on Nov 20, told of the origin, between 1917 and 1922, of the present health organisation of Russia It began, he said in a country devastated by war, revolution and counter-revolution, and the enemy at that time was the louse Typhus was spreading so rapidly that by 1919 Lenin knew that either socialism must defeat the louse or the louse would defeat socialism Dr Semashko had been appointed as the first people's commissar of public health, and an account of the problems he had to face in those early years appeared in our columns in 1920[1] The slogan chosen to launch the new health programme was this "The health of the people is the task of the people themselves"

As early as 1918 the programme of the U S S R included a comprehensive series of health and sanitary measures Mayakovsky and a group of young fellow poets left their verses to chalk health slogans on walls all over Russia They set the pace during that early period of the health revolution, and their inspiration has carried over into these days Dr Lipmann-Kessel told how he had visited a mother and child welfare clinic in Moscow in recent years Young medical women were taking the mothers round and explaining the anatomy and physiology of maternity to them with the aid of fine charts and models In the midst of them was a group of Red Army soldiers receiving a lecture from a woman doctor on the same topic, paternal responsibility in Russia includes education in the hygiene of maternity Respect for health is taught early In the schools the children covet the post of health inspector Two children in each class are appointed to this position and they not only make sure that the windows are open and that each child brings a clean handkerchief to school, but have charge of a health register which they keep up to date If any child stays away the children health inspectors visit his home, find out why, and carry a report back to the health officer at the school There are also health conferences for children, and they are taught public health as part of their curriculum

Every kind of medical treatment is given free of cost to every citizen who needs it The basis of the service is not, as with us, the general practitioner working alone, but the health centre, staffed by a group of doctors, specialists and nurses and equipped with facilities for diagnosis Health centres are placed in the factories, the suburbs, the collective farms or anywhere else where they are needed In Moscow, at the Stalin motor works, which employs 35,000 workers, there is a network of first-aid posts, as well as six visiting centres which those with minor injuries and disabilities can attend for treatment For those with more serious troubles there is the central polyclinic, staffed with 124 whole-time doctors and 18 dentists, who are responsible for the health of the workers This accent on health is no polite fiction, in Russia promotion of doctors depends on the standard of health among workers in their charge, and on a falling level in the time lost at work The graphs plotted to show progress are of health achieved, not of sickness overcome, and the polyclinic is responsible for the prevention, diagnosis and treatment of all disease within its area

Between 1919 and 1923 the probability of sickness in Russia was high · most of the people were ill or likely to become ill They were impoverished, famine stricken and disease ridden, and on this foundation of a sick population one of the greatest experiments in health services was built It is meaningless, Dr Lipmann-Kessel believes, to compare the number of hospital beds available in England with the number in Russia, per head of population we still have the lead in beds But a more significant figure, he suggested, was the threefold increase of beds in Russia during the last ten years In the same period the number of doctors has been nearly doubled A Russian institution which we should do well to copy at once, he thought was the night sanatorium Between full incapacity and full capacity there is often a transition period when a man is not fit to do a whole increase in bronchial-tract secretion was reported in rabbits when the animals received a gramme of powdered ipecacuanha per kilo body-weight On this basis, a man weighing 75 kg would get a dose of 75 g (gr 1125) of the drug, which is 562 times the maximum pharmacopœial dose of powdered ipecacuanha, and equivalent to 2½ pints of the tincture When it is recalled that a wine glassful of tincture of ipecacuanha administered to the human subject almost invariably results in vomiting accompanied by bronchorrhœa, salivation and sweating, the only conclusion that can be drawn from the experiments reported by Perry and Boyd is that rabbits and cats are extraordinarily tolerant of this and other emetics No reference is made to the occurrence of vomiting among the cats, but the passiveness of the rabbits is partly accounted for by the inability of these rodents to vomit There is, of course, the additional factor that all of the animals were under a general anæsthetic during the experiments We are not likely to make much progress in investigating the clinical value of expectorants if research is carried out on laboratory animals instead of patients with respiratory diseases The physician who is in daily contact with his patients is soon made to realise that he must concern himself only with subnauseating doses of expectorants Measurement *of the output of sputum in wide graduated test-tubes* does not entail much trouble and is sufficiently reliable if the intelligent cooperation of the patient can be relied on Bronchial fistulæ discharging measurable amounts of secretion from the respiratory tract would provide excellent experimental conditions, and the opportunities offered by patients suffering from gunshot wounds of the chest should be seized in order to throw more light on the efficacy of expectorants

RUBBER DERMATITIS

RUBBER is a popular constituent of footgear because of its hard wearing properties, its cheapness and the protection it offers against damp Some people, however, may become hypersensitive to rubber, responding with dermatitis of the feet to the use of rubber-soled shoes, or even shoes in which the insole has been impregnated with rubber This hypersensitivity has long been recognised, since dermatitis is specially prevalent in the rubber trade P V Marcussen, who has carried out an investigation[1] in Denmark, recalls recent work showing that the chemical accelerators used in the hot vulcanisation of rubber may be responsible for such sensitisation, and mentions the finding of P Bonnevie that in a series of factory cases the accelerator causing the trouble was invariably mercaptobenzothiazol Marcussen himself tested for rubber sensitivity all cases of dermatitis of the feet attending the skin department of the Copenhagen Finsen Institute over a period of 5 months The patients were first examined for mycotic or trichophytic infections, after which a patch of warm vulcanised rubber was applied to the right leg If there was no reaction similar tests were carried out with material from the patient's own shoes and with various chemical accelerators used in the rubber trade Of 102 patients with dermatitis of the feet, 11 (10%) were hypersensitive to rubber and the history was similar in many of these cases One boy of 12 for example, had three attacks of dermatitis between 1938 and 1940, all of which were associated with the use of rubber shoes The first attack had been treated as impetigo bullosa, caused by wearing plimsols and had disappeared in a fortnight in the second attack he was treated for epidermophyton interdigitale,' the trichophytin reaction at that time being strongly positive but the mycotic test negative, this also cleared in a fortnight, but three months later he had a more severe attack in which warm vulcanised rubber gave a strongly positive reaction The eruption became worse when the dressings included sheeting and improved as soon as this was oiled silk Another patient, a woman of 51, irritation due to a pair of rubber garters before She had replaced them with another rubber—and had had no further trouble until before she was examined, when she had cheap shoes, apparently made of leather, which much irritation of the feet She had worn sl time and the irritation had cleared up, but aft spent a few hours in rubber boots, on washing rash broke out, this failed to improve on which included a rubber bandage, and she gave a reaction to hot vulcanised rubber The soles of shoes turned out to be made of a mixture of rubber—a favourite combination, it seems, of cheap shoes She subsequently had attacks wore shoes with rubber-impregnated insoles, over low-cut shoes, or shoes with an elastic gusset strap, she gave negative results to trychoph mycosis tests throughout A third highly s case developed an attack after standing for a moments on a rubber mat after a bath The appear to be commoner in summer, either because footgear is then in more general use or because the of accelerator substance present in the rubber are re more freely at higher temperatures Age and sex to make no difference to incidence, there is no of family predisposition and as a rule no history of prev ous intolerance to rubber In 8 of the 11 cases attack appeared within 1–7 days of contact with rubber, in only one patient was the interval as 3 weeks Previous attacks, numerous in some had occurred in 5 and had lasted 3–6 weeks The toe affected in all cases and in 5 there was also spread to dorsal, and in 5 to the plantar, surface of the foot, heel was affected in one case An eruption also app on the hands in 6 cases, and one had generalised titis Thus the site of the lesions does not help in differential diagnosis between rubber dermatitis, myc and epidermophytosis In 7 of the 11 cases epider phytosis had actually been diagnosed in attacks, the series does not indicate whether a prece attack of epidermophytosis has any significance in ætiology of rubber dermatitis, but the fact that myc tests were always and trichophyton tests negative suggests that any connexion of the kind unlikely The incidence of rubber dermatitis is rare comparison with the prevalence of rubber soled foo But the patients affected, though few, are at a disadvantage, Marcussen thinks, partly because diagnosis may be missed and the shoes causing trouble may not be discarded, or the condition may aggravated by the use of dressings containing and partly because prophylaxis is difficult in women's shoes often have insoles containing rul or held in position by rubber solution, and this may overlooked or give rise to fresh attacks

[1] *Nordisk Med* Sept 6, 1941 p 2507

Mr F C BARTLETT, F R S, professor of psychology in the University of Cambridge, has appointed a member of the Medical Research Council succession to the late Prof A J Clark

The latest list of subscriptions to the Medical Relief Fund brings the total amount contributed to £35,000 Up to last September the distribution mittee, of which Sir Hugh Lett is chairman, had out over £8000 (*not £5000 as stated in* THE LANCET Nov 22)

On Wednesday, Dec 3, at 3 P M, Sir David Munro, medical officer of the Ministry of Supply, will open a medical department at the Longbridge works of the Motor Company of the pen So far as we can see all future board- may cease at the end of any week with no notice at t it often happens that two-thirds of our working s taken up by it and we must regulate our other ties accordingly We cannot, of course make the st guess at our income for more than a week ahead udgeting is out of the question "C'est la guerre," y sadly but in our hearts we fear it is only bureau-

We wonder whether a member of the Amalgam- Society of Bottle Washers or of any profession less up to meekness and longsuffering than our own, l be used quite like this by an elected government whether this is a fair sample of the promised golden of state medical service, but either from citizenship ome less noble motive we keep our complaints to elves and come and go as bid When peace comes oubt the Ministry will go to the Heralds' College for a of arms Meanwhile how would this do *Azure, a hercock revolvant or* with motto, *Varium et mutabile er?*

edical boards, 1939–41 as thousands of young men hundreds of doctors now know, are run on the Ford moving-belt system The candidate and his docu- nt pass down a row of four cubicles, each containing octor who does his bit, records his observations and his nion of the bit he has done and hands them on mber four not only does his own bit but reviews the k of those before him, considers the candidate as a rt of manhood, records his notion of a suitable grade, , with an "over to you over," sends him across the m to the chairman The chairman rapidly surveys the recorded facts and opinions and the candidate mself reaches a decision and records it If he finds mself differing substantially from other members of the ard he consults with them and endeavours, usually th success, to reach an agreed decision He and the ole board work according to instructions which are some matters extremely precise, in others quite definite As to the bits, those who first allotted them em to have had it in mind that the members of the oard would be what are termed "physicians-and- rgeons" and should accordingly be treated each to a crap of medicine and a scrap of surgery How other- ise would the astonishing assortment of ears and hearing, urine and belly have fallen to number four? Experience has led to a more logical grouping of functions etween the members and finality may not yet have been eached, but it has all along been true that only number our and the chairman have either the duty or the oppor- unity of considering their man as a whole

When therefore, the eager doctor starts out for two onsecutive sessions of medical board widely different xperiences may lie before him He may spend the reater part of five hours in the rapid examination of amples of urine for albumin and sugar, relieved by ntervals for the terse and vivid description of every ariety of hair, complexion, eye, mole and scar He ay keep his joints supple by 30–60 performances of "up in the morning early" exercises vis-a-vis the same umber of mildly astonished recruits He may take istories, test vision and assess mentality against time, r he may make a rapid general medical survey and enjoy e sport of seeing if he can catch his colleagues out It ay occur to him that some of these occupations scarcely quire for their efficient performance the discipline of e medical curriculum and the experience of practice, , of course, he may find them a pleasant relief from ore responsible work On some days the number and ality of the candidates make the work easy for every ember of the board; on others it is laborious for all, ery laborious for some and quite impossible to get it one in anything like the allotted time Regarding the atter more broadly it is hard to know whether this Ford ethod is in the circumstances the best way of doing the ob Three good clinicians, one being chairman, with an nqualified assistant to weigh, measure, test urine and cord the police description, and with a proper allowance f time, could almost certainly do it better especially they were told how their assessments worked out when he men got into the Services But they too would have o divide the examination of the man and they might not nd it easy to devise an efficient and satisfying plan he present method does assure for each recruit a reason- bly complete examination, approximating to a prescribed standard, capable of rapid performance and as little dependent as may be on the personnel of the board, but those who do the work have almost no means of guessing whether their assessments do in fact conform to the needs of the Services There is at present no liaison between chairmen or members of boards and commanding officers or medical officers of Service units and it is obvious that there ought to be

From the point of view of the medical profession it is certainly worth noting that this is the manner in which the state in 1941 finds it natural to tackle a clinical problem It does it by what it would call a team of doctors, of whom at least three are employed in work which makes minimal demands on clinical skill judgment or experience—work far below the standard of which any good doctor is capable The notion that the board is a team is, of course, an illusion Three doctors round a table may form a team Four doctors in a row of cubicles working against time with a chairman at a table noting their findings and making a final decision may constitute a good little machine for rapid examination but is not and cannot be a team

What of the recruits and the clinical aspect of the work? Experience of the samples of the population seen in one corner of outer London over a period of eighteen months is obviously not enough for any large pronouncements, but it does amply justify the assertion that we have a large number of most admirable young men There are days when almost without exception the candidates fall obviously into the first class, and one comely, upstanding, muscular young man after another passes smoothly down the board, cheerful, alert, manifestly keen to be passed fit and making the least of any defects he may have These young men follow a great variety of trades, but the best, as might be expected are those who work with eye and hand out of doors—dockers, lorry drivers, builders of various kinds skilled artisans and their labourers Clerks are far less uniform as specimens of good manhood but the best of them are excellent, surpassing sometimes even the manual labourer No "C3" class of young man has passed under my eye, and I have seen no trace whatever of widespread malnutrition It would be ludicrous to suggest that these almost perfect physical specimens whose only common blemish is some degree of neglected dental caries were not, or had not as children been, well and sufficiently fed Among those in sedentary trades some even under thirty, are fat and flabby and no doubt their diet is at least in part to blame, but the undersized and the thin, the clinically "ill-nourished," are conspicuously rare Sometimes, however, the mysterious net which dips into the population, enmeshes its draft and pours it out before us, delivers the most astonishing assortment of what can only be called mixed duds, and on a bad day the collective impression can be most depressing These bad patches seem to have nothing in common except that the men are probably over thirty and have something amiss Bad sight, running ears, deafness, valvular lesions, chronic bronchitis, duodenal ulcers, malunited fractures, old poliomyelitis, deformities of the feet (congenital or acquired), varicose veins epilepsy parkinsonism, anxiety neurosis, mental defect—anything and everything that can unfit them for life and for military service they have and it is not clear why they all come at once It is like one of those car journeys when at each succeeding crossroads the lights turn red as you approach. No doubt some combination of occupation-group and age-group is the real answer, yet their occupations recorded on their papers seem varied enough What is very clear, and somewhat alarming, is the startling difference between the round-twenties and the near-forties on the one hand and the realisation that some poor, outworn old man of thirty-nine is twelve years younger than the examining doctor, who feels, and hopes he looks, still young and vigorous Life has used some of them very hard Putting war aside, is the same fate in store for "the many men, so beautiful"—those young fitters, bricklayers and lorry-drivers' mates that we saw yesterday, or is the contrast a witness to one of the small waves of progress on the ebbing tide of our civilisation?

Sociology apart there is good exercise in rapid diagnosis to be had by those members of the board who are free to survey the man as a whole and daily lessons in the curiosities and unsolved mysteries of medicine and in that day's work or a heavy job but when he would be the better for doing something In the U S S R the man returning to work is examined at the factory clinic and allocated to a suitable job, for a suitable number of hours daily After work he goes to the night sanatorium where he is under the care of doctors and nurses and is given the food he needs Tests to estimate his response to return to work can be carried out, and his work is graded to meet his recovery

The casualty service in Moscow is also fully organised An emergency hospital serves an entire region, taking in every urgent case The telephone calls reporting cases are taken by a highly skilled member of the medical staff who, on the strength of what he is told, decides whether to send the emergency ambulance, which is express, or one of the ordinary ambulances If the express ambulance is sent, its moment of departure is recorded by the breaking of a light beam and its return is checked in the same way Every week the times taken on calls are analysed and any unexplained delay is investigated The young doctor who goes out with the ambulance is expected to make a quick diagnosis and to record it in a book His diagnoses are checked against the hospital findings, and the man who perpetually makes wild diagnoses can thus be detected

Dr Lipmann-Kessel reminded his hearers of the service Soviet research into the storage of blood had been to us in this war, and recalled Russian work on blood taken from the cadaver Russians have also perfected a technique of blood-transfusion for use in the front line , and their use of aerial transport for the wounded saved many lives in the Finnish campaign He described an ambulance tank which can be taken on to the battlefield and manœuvred to cover the wounded man, who is then lifted in through a sliding panel in the floor Thus the wounded can be retrieved without danger to stretcher-bearers

Pavlov spoke of Russia as the only country in the world where research could be carried on unfettered by economic ties This principle is carried into medical education , medical students are chosen only from among the best students , they receive free education and free books, and are paid during training like any other worker in the Soviet

SCOTLAND

EDUCATION OF CRIPPLES

Dr G J I Linklater, school medical officer for Edinburgh, speaking at a recent meeting of the Cripples Welfare Association said that the surgeon could now work wonders with the crippled child, but after he had done his best the child was put into the world with other children who had had full facilities for education The crippled child had been losing each year and education must be provided to bring him up to as high a scholastic standard as possible Muscles which had been altered by surgery must also be re-educated, and children who were unable to follow ordinary pursuits and exercises must receive psychological education Unless the inferiority complex were counteracted it would follow the child into life, with the further development of the timid person afraid to compete with his peers, the recessive person who would not establish social contacts, or the unlovable person who tried to overcome his limitations by over-compensation Dr Linklater drew attention to an obstacle which arose in relation to occupational therapy, when people who had been trained were not accepted by trade-unions because they had not served an apprenticeship Although they were competent workmen they had great difficulty in obtaining employment The visiting teacher was a great stimulus to the children who learned to read, write and make contact with the outside world They were taught to use their hands, and their attention was taken away from their disability Unfortunately this had ceased with the war but he hoped it would begin again

PART-TIME MISSIONARY

Dr F M Graham, who died in Edinburgh on Nov 17 at the age of 71 was for many years a medical missionary in India He took the Scottish triple qualification in 1890, his F R C S E in 1895, and the M D of Durham in 1906 For some time he acted as tutor in clinical surgery and clinical assistant in the medical department of the Edinburgh Royal Infirmary physician to the Cowgate Dispensary He examiner in anatomy to the Royal College of of Edinburgh At the end of last century he India where, working as a free lance, he medical missionaries in the winter and in the hot practised in the hill stations But his health robust and he was forced to return to this country ever he followed the same plan of working, in Britain during the summer and in the Church Society's hospital in Old Cairo in the winter D last war he worked as a civilian doctor in France and for his services was created chevalier Legion d'Honneur Dr Graham's wife died a few

In England Now

A Running Commentary by Peripatetic Corresp

STRUCK down by a virulent organism which on me unnoticed, I was dispatched to a certain Defence Sick Bay. Surrounded by comfort and attention I made a quick recovery and soon critical stage, by which I mean the stage when the begins to criticise his treatment The only could raise was that I was aroused at a quarter to in the morning As insomnia was a feature of the the point was an acute one It was only slight tion to recall that in previous experiences of general Service hospitals and nursing-homes the h had been still earlier Discussions with the sister duced the familiar arguments that everything had to be cleaned up before the doctor came, and unless an start was made the work would never be done , it was the traditional hospital practice I stonily unconvinced As a physician it matters to me whether a hospital patient has had his face before I call or not A rearrangement of organ could ensure that the work could be completed if it started later It is unjustifiable to assume (as is done) that a tradition is ipso facto good Like another I customarily go to bed between 12 and 1 and about 8 Surely the average patient, and more culararly the sufferer from insomnia, does not derive special benefit from such a drastic change of habit wh puts out the lights at 9 o'clock and rouses him at even earlier I have always held the view that patie were more important than physicians in the although such an opinion may seem heterodox in quarters I have even thought (though I would not to say so without the blessed cloak of anonymity) the H P was really more important than the honor At least, he does the bulk of the work, although of it is under direction All this being so there does ground for re-examining the position, and as a final a personal experience might be quoted In several instances when my patients could not sleep, I have that screens should be put round the bed and that should not be disturbed in the morning under any cumstances until he awoke This " eccentricity" mine was singularly unpopular with the ward sister, the results for the patient were so satisfactory insisted and persisted

* * *

Those of us who formerly practised and must still and support our families in the morally devastated of London once known as " good residential neigh hoods " cannot but be grateful to the Ministry of and National Service for employing us usefully on medical boards and paying us for our work , but we sometimes that we could have a little friendly talk the minister about the way his ministry orders its and ours Some matters are so curiously or The most curious is the wildly irregular incidence boards The vagaries of the weather, the whims women and the arrhythmia of auricular fibrillation nothing to it There was a time last year when for se weeks on end a weekly routine was actually but those days are gone, we suppose for ever, and we accept, like good children, three days' notice of week's sessions—which may vary from six or eight one or none—and are not unduly put about when, nine sessions actually allotted us are cancelled at

f the pen   So far as we can see all future board-
ay cease at the end of any week with no notice at
it often happens that two-thirds of our working
taken up by it and we must regulate our other
es accordingly   We cannot of course, make the
guess at our income for more than a week ahead
dgeting is out of the question   "C'est la guerre,"
sadly but in our hearts we fear it is only bureau-
We wonder whether a member of the Amalgam-
ociety of Bottle Washers, or of any profession less
ıp to meekness and longsuffering than our own,
be used quite like this by an elected government
hether this is a fair sample of the promised golden
state medical service, but either from citizenship
ne less noble motive we keep our complaints to
lves and come and go as bid   When peace comes

er?

dical boards, 1939–41, as thousands of young men
hundreds of doctors now know are run on the Ford
ıoving-belt system   The candidate and his docu-
, pass down a row of four cubicles each containing
tor who does his bit, records his observations and his
ion of the bit he has done and hands them on
ıber four not only does his own bit but reviews the
of those before him, considers the candidate as a
of manhood, records his notion of a suitable grade,
with an "over to you, over," sends him across the
ı to the chairman   The chairman rapidly surveys
he recorded facts and opinions and the candidate
self, reaches a decision and records it   If he finds
self differing substantially from other members of the
rd he consults with them and endeavours, usually
h success, to reach an agreed decision   He and the
ole board work according to instructions which are
some matters extremely precise, in others quite
lefinite   As to the bits, those who first allotted them
m to have had it in mind that the members of the
ard would be what are termed "physicians-and-
rgeons" and should accordingly be treated each to a
rap of medicine and a scrap of surgery   How other-
ıse would the astonishing assortment of ears and
earing, urine and belly have fallen to number four?
xperience has led to a more logical grouping of functions
etween the members and finality may not yet have been
ached but it has all along been true that only number
ur and the chairman have either the duty or the oppor-
ınity of considering their man as a whole

When, therefore, the eager doctor starts out for two
onsecutive sessions of medical board widely different
xperiences may lie before him   He may spend the
eater part of five hours in the rapid examination of
ımples of urine for albumin and sugar, relieved by
tervals for the terse and vivid description of every
ariety of hair, complexion, eye, mole and scar   He
ay keep his joints supple by 30–60 performances of
up in the morning early" exercises vis-a-vis the same
ımber of mildly astonished recruits   He may take
stories, test vision and assess mentality against time,
he may make a rapid general medical survey and enjoy
e sport of seeing if he can catch his colleagues out   It
ay occur to him that some of these occupations scarcely
quire for their efficient performance the discipline of
e medical curriculum and the experience of practice,
of course, he may find them a pleasant relief from
ore responsible work   On some days the number and
ıality of the candidates make the work easy for every
ember of the board, on others it is laborious for all,
ry laborious for some and quite impossible to get it
ne in anything like the allotted time   Regarding the
atter more broadly it is hard to know whether this Ford
ethod is in the circumstances the best way of doing the
   Three good clinicians, one being chairman, with an
qualified assistant to weigh, measure, test urine and
cord the police description, and with a proper allowance
time, could almost certainly do it better especially
they were told how their assessments worked out when
e men got into the Services   But they too would have
divide the examination of the man and they might not
nd it easy to devise an efficient and satisfying plan
he present method does assure for each recruit a reason-
bly complete examination, approximating to a prescribed standard, capable of rapid performance and as little dependent as may be on the personnel of the board but those who do the work have almost no means of guessing whether their assessments do in fact conform to the needs of the Services   There is at present no liaison between chairmen or members of boards and commanding officers or medical officers of Service units and it is obvious that there ought to be

From the point of view of the medical profession it is certainly worth noting that this is the manner in which the state in 1941 finds it natural to tackle a clinical problem   It does it by what it would call a team of doctors, of whom at least three are employed in work which makes minimal demands on clinical skill, judgment or experience—work far below the standard of which any good doctor is capable   The notion that the board is a team is, of course, an illusion   Three doctors round a table may form a team   Four doctors in a row of cubicles working against time with a chairman at a table noting their findings and making a final decision may constitute a good little machine for rapid examination but is not and cannot be a team

What of the recruits and the clinical aspect of the work? Experience of the samples of the population seen in one corner of outer London over a period of eighteen months is obviously not enough for any large pronouncements, but it does amply justify the assertion that we have a large number of most admirable young men   There are days when almost without exception the candidates fall obviously into the first class, and one comely, upstanding, muscular young man after another passes smoothly down the board, cheerful, alert, manifestly keen to be passed fit and making the least of any defects he may have   These young men follow a great variety of trades, but the best, as might be expected are those who work with eye and hand out of doors—dockers, lorry drivers, builders of various kinds, skilled artisans and their labourers   Clerks are far less uniform as specimens of good manhood but the best of them are excellent, surpassing sometimes even the manual labourer   No "C3" class of young man has passed under my eye, and I have seen no trace whatever of widespread malnutrition   It would be ludicrous to suggest that these almost perfect physical specimens whose only common blemish is some degree of neglected dental caries were not, or had not as children been, well and sufficiently fed   Among those in sedentary trades some even under thirty, are fat and flabby and no doubt their diet is at least in part to blame, but the undersized and the thin, the clinically "ill-nourished," are conspicuously rare   Sometimes, however, the mysterious net which dips into the population, enmeshes its draft and pours it out before us, delivers the most astonishing assortment of what can only be called mixed duds, and on a bad day the collective impression can be most depressing   These bad patches seem to have nothing in common except that the men are probably over thirty and have something amiss   Bad sight, running ears, deafness, valvular lesions, chronic bronchitis, duodenal ulcers, malunited fractures, old poliomyelitis, deformities of the feet (congenital or acquired), varicose veins, epilepsy, parkinsonism, anxiety neurosis, mental defect—anything and everything that can unfit them for life and for military service they have and it is not clear why they all come at once   It is like one of those car journeys when at each succeeding cross-roads the lights turn red as you approach   No doubt some combination of occupation-group and age-group is the real answer, yet their occupations recorded on their papers seem varied enough   What is very clear, and somewhat alarming, is the startling difference between the round-twenties and the near-forties on the one hand and the realisation that some poor outworn old man of thirty-nine is twelve years younger than the examining doctor, who feels, and hopes he looks, still young and vigorous   Life has used some of them very hard   Putting war aside, is the same fate in store for "the many men, so beautiful"—those young fitters, bricklayers and lorry-drivers' mates that we saw yesterday, or is the contrast a witness to one of the small waves of progress on the ebbing tide of our civilisation?

Sociology apart there is good exercise in rapid diagnosis to be had by those members of the board who are free to survey the man as a whole, and daily lessons in the curiosities and unsolved mysteries of medicine and in that day's work or a heavy job but when he would be the better for doing something In the U S S R the man returning to work is examined at the factory clinic and allocated to a suitable job, for a suitable number of hours daily After work he goes to the night sanatorium where he is under the care of doctors and nurses and is given the food he needs Tests to estimate his response to return to work can be carried out, and his work is graded to meet his recovery

The casualty service in Moscow is also fully organised An emergency hospital serves an entire region, taking in every urgent case The telephone calls reporting cases are taken by a highly skilled member of the medical staff who, on the strength of what he is told, decides whether to send the emergency ambulance, which is express, or one of the ordinary ambulances If the express ambulance is sent its moment of departure is recorded by the breaking of a light beam and its return is checked in the same way Every week the times taken on calls are analysed and any unexplained delay is investigated The young doctor who goes out with the ambulance is expected to make a quick diagnosis and to record it in a book His diagnoses are checked against the hospital findings, and the man who perpetually makes wild diagnoses can thus be detected

Dr Lipmann-Kessel reminded his hearers of the service Soviet research into the storage of blood had been to us in this war, and recalled Russian work on blood taken from the cadaver Russians have also perfected a technique of blood-transfusion for use in the front line, and their use of aerial transport for the wounded saved many lives in the Finnish campaign He described an ambulance tank which can be taken on to the battlefield and manœuvred to cover the wounded man, who is then lifted in through a sliding panel in the floor Thus the wounded can be retrieved without danger to stretcher-bearers

Pavlov spoke of Russia as the only country in the world where research could be carried on unfettered by economic ties This principle is carried into medical education, medical students are chosen only from among the best students, they receive free education and free books, and are paid during training like any other worker in the Soviet

SCOTLAND

EDUCATION OF CRIPPLES

Dr G J I Linklater, school medical officer for Edinburgh, speaking at a recent meeting of the Cripples Welfare Association said that the surgeon could now work wonders with the crippled child, but after he had done his best the child was put into the world with other children who had had full facilities for education The crippled child had been losing each year and education must be provided to bring him up to as high a scholastic standard as possible Muscles which had been altered by surgery must also be re-educated, and children who were unable to follow ordinary pursuits and exercises must receive psychological education Unless the inferiority complex were counteracted it would follow the child into life, with the further development of the timid person afraid to compete with his peers, the recessive person who would not establish social contacts, or the unlovable person who tried to overcome his limitations by over-compensation Dr Linklater drew attention to an obstacle which arose in relation to occupational therapy, when people who had been trained were not accepted by trade-unions because they had not served an apprenticeship Although they were competent workmen they had great difficulty in obtaining employment The visiting teacher was a great stimulus to the children who learned to read, write and make contact with the outside world They were taught to use their hands, and their attention was taken away from their disability Unfortunately this had ceased with the war but he hoped it would begin again

PART-TIME MISSIONARY

Dr F M Graham, who died in Edinburgh on Nov 17 at the age of 71 was for many years a medical missionary in India He took the Scottish triple qualification in 1890, his F R C S E in 1895, and the M D of Durham in 1906 For some time he acted as tutor in clinical surgery and clinical assistant in the medical department of the Edinburgh Royal physician to the Cowgate Dispensary He examiner in anatomy to the Royal College of of Edinburgh At the end of last century he India where, working as a free lance, he medical missionaries in the winter and in the hot practised in the hill stations But his health robust and he was forced to return to this ever he followed the same plan of working, in Britain during the summer and in the Church Society's hospital in Old Cairo in the winter last war he worked as a civilian doctor in France and for his services was created chevalier Legion d'Honneur Dr Graham's wife died

In England Now

A Running Commentary by Peripatetic C

STRUCK down by a virulent organism which on me unnoticed, I was dispatched to a certain Defence Sick Bay. Surrounded by comfort and attention I made a quick recovery and soon critical stage, by which I mean the stage when begins to criticise his treatment The only could raise was *that I was aroused at a quarter to in the morning As insomnia was a feature of the* the point was an acute one It was only slight tion to recall that in previous experiences of Service hospitals and nursing-homes the ho had been still earlier Discussions with the sister duced the familiar arguments that everything had to cleaned up before the doctor came, and unless an start was made the work would never be done, it was the traditional hospital practice I stonily unconvinced As a physician it matters to me whether a hospital patient has had his face before I call or not A rearrangement of organ could ensure that the work could be completed if it started later It is unjustifiable to assume (as is done) that a tradition is ipso facto good Like another I customarily go to bed between 12 and 1 about 8 Surely the average patient and more par cularly the sufferer from insomnia, *does not derive* special benefit from such a drastic change of habit puts out the lights at 9 o'clock and rouses him at even earlier I have always held the view that were *more important than physicians* in the ho although such an opinion may seem heterodox in quarters I have even thought (though I would not to say so without the blessed cloak of anonymity) the H P was really more important than the hon At least, he does the bulk of the work, although of it is under direction All this being so there does ground for re-examining the position, and as a final a personal experience might be quoted In instances when my patients could not sleep, I have that screens should be put round the bed and should not be disturbed in the morning under any cumstances until he awoke This "eccentricity" mine was singularly unpopular with the ward sister, the results for the patient were so satisfactory insisted and persisted

* * *

Those of us who formerly practised and must still and support our families in the morally devastated of London once known as "good residential nei- hoods" cannot but be grateful to the Ministry of and National Service for employing us usefully medical boards and paying us for our work, but we sometimes that we could have a little friendly talk the minister about the way his ministry orders its and ours Some matters are so curiously The most curious is the wildly irregular incidence boards The vagaries of the weather, the whims women *and* the *arrhythmia* of auricular fibrillation nothing to it There was a time last year when for weeks on end a weekly routine was actually but those days are gone, we suppose for ever, and we accept, like good children, three days' notice of week's sessions—which may vary from six or eight one or none—and are not unduly put about when nine sessions actually allotted us are cancelled at eech Jones and Dr Morgan Apparently however, well as 'that very distinguished Colonial servant Hailey" is presiding over a committee dealing post-war colonial problems and so, presumably the er can be left in his hands In which case Medicus lined to ask why is he not appointed colonial secretary instead of Lord Moyne?

us kind of "waffling" is no good to the House and not interest the House—often only about 15 bers were present during the debate It is a grave ness of the procedure that this should be possible, he acid test of our belief in democracy will be our tment of the Colonies and India—and that is another

FROM THE PRESS GALLERY

Our Colonial Responsibilities

the fifth day of the customary debate on the lress which was devoted to colonial affairs, much ss was laid on nutrition for, as Mr J A E de Roths-ld pointed out, vitamins and protein are equally essary to black and white Yet the malnutrition in ts of our Empire is still our greatest social folly Mr el Baker thought that we had made progress but in many colonies there was still too much poverty, orance and preventable diseases Exploitation of our and of national resources were not only a social ne but also a social waste, and the Colonial Development and Welfare Act passed last year was our first ctive step to check the waste He was glad that the onial Office was planning for the future but there were ent tasks lying to hand The tsetse fly in Africa was e, and he suggested that we should cooperate at once th our Free French and Belgian allies, put up a sum money from our Colonial Development Fund, and call the health section of the League of Nations to organise search and make a start on practical work Dr H B organ, who was brought up in the West Indies raised medical storm with his speech on conditions there s a doctor, he said he had seen too many people playing ith bandages rather than dealing with the general onditions which underlie the sores, and he was pessimistic about any benevolent policy unless the people on the spot were given a chance, with whatever reservations were necessary, to have some say in the control of local affairs He inveighed against a system which exported produce and imported heavily taxed food, while income-tax remained as low as *3d* to *2s 6d* in the £ When he visited Barbados in 1939 the people were living in a black cesspool of disease—yaws hookworm, syphilis, malaria and tuberculosis The Rockefeller Medical Commission had found instances of hookworm in two or three parishes in Trinidad amounting to 80–90% of the agricultural population The doctors in the West Indies are blamed for a medical policy with which they have nothing to do, instead of a unified medical service a doctor may not move from one parish to another, while some of the hospitals he had seen were a disgrace Mr Creech Jones deplored the decision of the Colonial Office not to publish the reports of the colonies and said hat our knowledge of their economic and social problems was hampered by a lack of vital statistics He urged he need for an expansion of the social services department of the Colonial Office and said he would like to see a arger number of expert women with understanding and drive brought into it He too stressed the need for the xhibition of greater vigour in the whole field of pre-entive medicine

Mr G H Hall, parliamentary secretary for the colonies, aid that at the beginning of the war we were approaching a critical period in colonial history, and while the war had in one sense delayed the crisis, in another sense it had hastened it The public conscience had been awakened to the need to take a more constructive nterest in the social, economic and spiritual welfare of he colonial peoples who were now solidly behind us in our war effort Our duty was to improve their lot to develop their resources so as to raise their standard of life, and to enable them to take an ever-increasing responsibility in ordering their own affairs

Agricultural Returns

On Nov 19 Mr R S Hudson, the minister of agri-ulture, said that the output of cereals and straw this year will be at least as much again as in peace-time The total area of crops resulting from the ploughing-up policy is about 45% above peace-time level The yield from the ploughed-up land has been extremely satisfactory, and the latest estimates of the production of root crops promise a good harvest, well above the average for the last ten years The production of potatoes will be just short of double the peace-time amount Farmers have almost maintained our pre-war milk-supply In 1938 they produced 1076 million gallons, this year we have 1053 million gallons But liquid milk consumed has gone up by 200 million gallons

QUESTION TIME

Health of the Nation

Dr Russell Thomas asked the Minister of Health if he would examine the standard of nourishment, housing, physical training and working conditions of the nation, with a view to satisfying himself as to whether they were sufficient to promote adequate natural resistance to major and minor diseases —Mr E Brown replied I do not think that general inquiries of this kind would usefully add to the continuous work of the Ministry The health of the nation and the resistance of the people to disease has up to now been good—even I can say unexpectedly good in view of the added risks brought about by war time conditions I have no doubt this is largely due to the improvements in social conditions since the first World War and our efforts to maintain and add to them will be sustained

Increase of Tuberculosis among Women

The latest available figures comparable with prewar years are those for 1940, when mortality among women from all forms of tuberculosis showed an increase of 11% over 1939 The highest incidence was in the age group 20–24, where the increase was 18% (Mr Brown replying to Mr James Griffiths)

Sale of Tuberculous Cows

Mr C T Culverwell asked the Minister of Agriculture whether cattle tuberculin tested by veterinary surgeons authorised by his ministry and found to be tuberculous were permitted to be sold as dairy cattle —Mr R S Hudson replied Yes The sale of cows reacting to the tuberculin test is not, on that account, restricted, since reaction to the test does not in itself imply infection in the milk of a reactor

Provision of School Meals

In answer to a question, Mr R A Butler, president of the Board of Education, said that 24 local education authorities in Wales provide school meals and 3 9% of the children attending public elementary schools in those areas receive meals at school There remain six areas—Radnorshire, Llanelly, Neath, Pembroke borough, Port Talbot and Pontypridd—in which no meals are yet being provided, but in all of them provision will shortly be ready or is under active discussion.

In answer to a further question, Mr J C Ede, parliamentary secretary to the board, replied On a single day in October midday dinners were provided for 21,729 children in the area of the West Riding of York authority This figure is an increase of 59 9% over the number provided on a day in February last

Wheatmeal Bread

Captain J D Profumo asked the parliamentary secretary to the Ministry of Food to what extent the original recommendations with regard to national wheatmeal bread, made by the Medical Research Council, were accepted, and on what grounds any of them were turned down.—Major G Lloyd George replied No recommendation made by the council with regard to national wheatmeal bread has been rejected All have been acted upon with one exception That is still being examined

Captain Profumo Is it not a fact that a standard as to the contents of the national wheatmeal loaf has never been laid down by the ministry—in regard to the amount of bran, &c —and are not the public being misled into thinking they are eating something of great value?

Major Lloyd George I am advised that a specification for the wheatmeal loaf has been laid down

Captain Profumo I believe the minister will find that that is not the case

Infection in Labour Camps

Sir Percy Hurd asked the Minister of Health what action he had taken upon the report sent to him last month by the still neglected science, clinical physiology What is the real explanation of that quiet mitral stenosis which we cheerfully dismiss as rheumatic, though no faintest history of rheumatism, chorea, scarlet fever or any illness whatever can be dragged from the victim even by leading questions ? Why do holes in the ear-drums and mess in the middle ear, let alone solid plugs of wax in the auditory meatus, affect the hearing so little ? What is the truth about the plantar arches ? Why did anyone ever suggest that there is a normal systolic blood-pressure between 110 and 160 or a normal pulse-rate between 48 and 120, and why, when we are listening to the blood-pressure noises, is there sometimes a point when they cease (which we then call the diastolic pressure) and sometimes none (when we say nothing about it) ? How very little cardiac efficiency is affected by valvular defects ! And did you know that one leg was so often shorter than the other ? Why do albuminuria and sometimes glycosuria come and go in such an extraordinary fashion, and why are quite athletic-looking young men unable to stretch out one foot without falling over ? Does the expansion of the chest vary inversely with the excellence of the physique or is it self-consciousness ?

In fact if you are lucky in your place on the board, and are not too violently pressed for time, the work has many compensations , but why, oh why, in the absence of Western Front battles or invasions can it not run steady for a fortnight on end ?

* * *

I wonder if others have this form of fantasy It might be termed " The Parliament of the Genes," and with me it sits when I am having a hot bath or early morning tea It is a huge parliament, about 2000 members on each side but is dominated by the front benches, the back-benchers being mostly mute The Government are parsons lawyers and farmers, while the maternal or opposition party are more commercial—shopkeepers, in trade or industry, a sailor or two There is also a small and noisy independent party whom I suspect of being mutations They have strange methods, this assembly , sometimes they talk in blank verse or rhyme, or rock like a Greek chorus , sometimes somebody says a line or two, and then they all sit for many baths and cups of tea and never say a word, just ruminate about it The subjects they discuss are rather vague and diffuse—for instance, for the last twenty years or so they have been arguing on and off whether it is better for a boy to have natural history hobbies or, as most modern children prefer, mechanical ones and this often broadens out into Agriculture *v* Industry An excerpt from Hansard might run like this

The P M (a clerical figure with a white stock, in a Gregorian chant) Are not the works of the Lord greater than those of Armstrong Whitworth, white mice than Meccano ? Moreover, if wheels do your work, the best that is in you will not be developed by muscle and sinew

A very old Opposition back bencher We heard that old story before, when arboreal man from a cleft in a stick first threw a stone at a tiger, or again in a later debate on the first bow and arrow Yet, see where they got us !

P M (continuing) The man in machines is half drowned by the grime and the greed of his calling , his lights and fertility wilt in the stench of their rapid explosions

Independent member Are mice the most scentless of beasts and pigs without their aroma ?

The Opposition break into a chorus This is a mechanistic age and he who would get on must mechanistic be, And on mechanics must his mind be set That is the quickest way to L s d , And to Debrett

Independent member The limitations of your L s d are 1 wife, 1 house and 3 square meals per d , Children to taste The surplus is pure waste

P M The happiness that comes from natural things is greater far

Leader of the Opposition Is happiness our goal ? Like cows and cabbages, should man too seek content and rest from searching ?

A sailor sitting next to him Searching the surface of this earth of ours, searching its inner core, its outer skies, with all five senses, banded, making more, to scour the firmament that yonder lies beyond this speck of planetary dust

Independent member Come off it, Jack, we've heard that speech before—you gave it at the last Rotarian lunch

The debate continues—and probably will till I die

Parliament

ON THE FLOOR OF THE HOUSE

MEDICUS M P

THE list of contents on the outer cover of Hansard for Nov 19 begins, as usual, with Questions, then goes on to Mr Speaker's Golden Wedding Congratulatory Tributes and ends with King's Speech (Fourth Day) Agriculture Nevertheless, in rising to congratulate the Speaker the Prime Minister apologised for committing " an irregularity " No speaker of the House as far back as 1653 has ever reached his golden wedding while in office And before 1653, Mr Churchill pointed out, occupants of the chair " held their tenure for shorter and more precarious periods " The Prime Minister spoke of the affection of the House for the Speaker and his family, of their belief in his impartiality and of his kindliness and courtesy to members of all parties, and gave notice of a presentation to be made by a delegation of members headed by the Father of the House, Mr Lloyd George, later in the day Mr Pethick-Lawrence spoke for the Labour M P s, Sir Percy Harris for the little Liberal group, Mr Will Thorne as the oldest member in age, and Mr Maxton as the leader of the smallest minority in the House The best speech, almost the perfect speech in the old Parliamentary manner, was made by Mr Maxton, himself a professed rebel The Speaker's reply was equally gracious and ended as it was bound to do, for it is the sacrosanct formula in opening the day's business " The Clerk will now proceed to read the Orders of the Day "

* * *

The forms of the House continue but the change in the content of discussion in the House is very great indeed Some of this takes place outside the House, in public statements by ministers and others, as it always did Mr Maisky for Soviet Russia, and Mr Eden for the British Commonwealth, speak of close cooperation after the war—and a revolution in thought is accomplished which would have been inconceivable as practical politics up to a few months ago Our cooperation with the United States, involving the surrender of cherished colonial rights in the West Indies, Central America and elsewhere had, even before the Atlantic Charter, opened up an unknown new road into the future The days when Mr Chamberlain could refer to Czecho Slovakia as being " far off " are difficult to understand in days when the road from Burma to China is an objective of urgent consideration to the Government sitting in London

But while conceptions are bigger than in the past and new horizons have opened, many of the old conceptions of government and preconceptions of the position of this country vis-à-vis others remain The debate on colonial affairs on Nov 20 showed this very clearly It was opened by Mr Noel Baker in a speech reminiscent of the days of 1919 when, as he said, " we were drafting the Mandates " at the Paris peace conference Sir Ronald Ross said that the suggestion that the mandatary system was a success " rather shook " him and called it " as good escapist literature as it is possible to find " Mr Baker's speech was a great deal more than that, as it gave a big-scale survey of some of the main colonial problems, although Dr Morgan said its optimism rather perturbed him Dr Morgan, however, came down to earth and said we should put the Colonial Office in the dock The indictment was severe and presented by a man who was brought up in the West Indies and knows the country Failure to make constitutional changes of a democratic kind was important inasmuch as " these voteless, helpless people " (of Barbados) " cannot do anything themselves to change their conditions, because they have not the power to introduce any legislation to change their social or economic conditions " To do anything in the West Indies it was necessary to " throttle the private land monopoly " and get down to subsistence agriculture instead of concentrating on export agriculture

Mr George Hall, under-secretary for the Colonies, replying, uttered some platitudes about the need for " a far greater and more constructive interest in the social, economic and spiritual welfare of the colonial peoples," but failed to reply to the criticisms of Mr Noel Baker, Mr Creech Jones and Dr Morgan Apparently however, all is well as "that very distinguished Colonial servant, Lord Hailey' is presiding over a committee dealing with post-war colonial problems and so, presumably the matter can be left in his hands In which case Medicus is inclined to ask why is he not appointed colonial secretary instead of Lord Moyne?

This kind of "waffling" is no good to the House and does not interest the House—often only about 15 members were present during the debate It is a grave weakness of the procedure that this should be possible, for the acid test of our belief in democracy will be our treatment of the Colonies and India—and that is another story

FROM THE PRESS GALLERY

Our Colonial Responsibilities

In the fifth day of the customary debate on the Address which was devoted to colonial affairs, much stress was laid on nutrition for as Mr J A E de Rothschild pointed out, vitamins and protein are equally necessary to black and white Yet the malnutrition in parts of our Empire is still our greatest social folly Mr Noel Baker thought that we had made progress but in too many colonies there was still too much poverty, ignorance and preventable diseases Exploitation of labour and of national resources were not only a social crime but also a social waste, and the Colonial Development and Welfare Act passed last year was our first effective step to check the waste He was glad that the Colonial Office was planning for the future but there were urgent tasks lying to hand The tsetse fly in Africa was one, and he suggested that we should cooperate at once with our Free French and Belgian allies put up a sum of money from our Colonial Development Fund, and call in the health section of the League of Nations to organise research and make a start on practical work Dr H B Morgan, who was brought up in the West Indies, raised a medical storm with his speech on conditions there As a doctor, he said he had seen too many people playing with bandages rather than dealing with the general conditions which underlie the sores, and he was pessimistic about any benevolent policy unless the people on the spot were given a chance, with whatever reservations were necessary, to have some say in the control of local affairs He inveighed against a system which exported produce and imported heavily taxed food while income-tax remained as low as 3*d* to 2*s* 6*d* in the £ When he visited Barbados in 1939 the people were living in a black cesspool of disease—yaws hookworm, syphilis, malaria and tuberculosis The Rockefeller Medical Commission had found instances of hookworm in two or three parishes in Trinidad amounting to 80–90% of the agricultural population The doctors in the West Indies are blamed for a medical policy with which they *have nothing* to do, instead of a unified medical service a doctor may not move from one parish to another, while some of the hospitals he had seen were a disgrace Mr Creech Jones deplored the decision of the Colonial Office not to publish the reports of the colonies and said that our knowledge of their economic and social problems was hampered by a lack of vital statistics He urged the need for an expansion of the social services department of the Colonial Office and said he would like to see a larger number of expert women with understanding and drive brought into it He too stressed the need for the exhibition of greater vigour in the whole field of preventive medicine

Mr G H Hall, parliamentary secretary for the colonies, said that at the beginning of the war we were approaching a critical period in colonial history, and while the war had in one sense delayed the crisis, in another sense it had hastened it The public conscience had been awakened to the need *to* take a more constructive interest in the social, economic and spiritual welfare of the colonial peoples who were now solidly behind us in our war effort Our duty was to improve their lot, to develop their resources so as to raise their standard of life, and to enable them to take an ever-increasing responsibility in ordering their own affairs

Agricultural Returns

On Nov 19 Mr R S Hudson, the minister of agriculture, said that the output of cereals and straw this year will be at least as much again as in peace-time The total area of crops resulting from the ploughing-up policy is about 45% above peace-time level The yield from the ploughed-up land has been extremely satisfactory, and the latest estimates of the production of root crops promise a good harvest, well above the average for the last ten years The production of potatoes will be just short of double the peace-time amount Farmers have almost maintained our pre-war milk-supply In 1938 they produced 1076 million gallons, this year we have 1053 million gallons But liquid milk consumed has gone up by 200 million gallons

QUESTION TIME

Health of the Nation

Dr Russell Thomas asked the Minister of Health if he would examine the standard of nourishment, housing, physical training and working conditions of the nation, with a view to satisfying himself as to whether they were sufficient to promote adequate natural resistance to major and minor diseases —Mr E Brown replied I do not think that general inquiries of this kind would usefully add to the continuous work of the Ministry The health of the nation and the resistance of the people to disease has up to now been good—even I can say unexpectedly good in view of the added risks brought about by war-time conditions I have no doubt this is largely due to the improvements in social conditions since the first World War and our efforts to maintain and add to them will be sustained

Increase of Tuberculosis among Women

The latest available figures comparable with prewar years are those for 1940, when mortality among women from all forms of tuberculosis showed an increase of 11% over 1939 The highest incidence was in the age-group 20–24, where the increase was 18% (Mr Brown replying to Mr James Griffiths)

Sale of Tuberculous Cows

Mr C T Culverwell asked the Minister of Agriculture whether cattle tuberculin tested by veterinary surgeons authorised by his ministry and found to be tuberculous were permitted to be sold as dairy cattle —Mr R S Hudson replied Yes The sale of cows reacting to the tuberculin test is not, on that account, restricted, since reaction to the test does not in itself imply infection in the milk of a reactor

Provision of School Meals

In answer to a question, Mr R A Butler, president of the Board of Education, said that 24 local education authorities in Wales provide school meals and 3 9% of the children attending public elementary schools in those areas receive meals at school There remain six areas—Radnorshire, Llanelly, Neath, Pembroke borough, Port Talbot and Pontypridd—in which no meals are yet being provided, but in all of them provision will shortly be ready or is under active discussion

In answer to a further question, Mr J C Ede, parliamentary secretary to the board, replied On a single day in October midday dinners were provided for 21,729 children in the area of the West Riding of York authority This figure is an increase of 59 9% over the number provided on a day in February last

Wheatmeal Bread

Captain J D Profumo asked the parliamentary secretary to the Ministry of Food to what extent the original recommendations with regard to national wheatmeal bread, made by the Medical Research Council, were accepted, and on what grounds any of them were turned down —Major G Lloyd George replied No recommendation made by the council with regard to national wheatmeal bread has been rejected All have been acted upon with one exception. That is still being examined

Captain Profumo Is it not a fact that a standard as to the contents of the national wheatmeal loaf has never been laid down by the ministry—in regard to the amount of bran, &c —and are not the public being misled into thinking they are eating something of great value?

Major Lloyd George I am advised that a specification for the wheatmeal loaf has been laid down.

Captain Profumo I believe the minister will find that that is not the case

Infection in Labour Camps

Sir Percy Hurd asked the Minister of Health what action he had taken upon the report sent to him last month by the

Wiltshire public health committee that the committee had been called upon to provide facilities for cases of vermin, scabies, venereal disease and advanced pulmonary tuberculosis among the imported labourers, especially from Ireland, for employment on Government contracts, and whether steps would be taken to ensure a strict medical examination before importation —Mr **Brown** replied Local consultations have taken place with all concerned regarding medical arrangements at the labour camps referred to The county council's medical officer is giving valuable assistance and the necessary measures are in train The point raised in the last part of the question is being considered in conjunction with the Ministry of Labour and National Service

Sale of Horseflesh

In reply to a question, Major **Lloyd George** said that shops selling horseflesh for human consumption require to be licensed Those selling horseflesh for consumption by animals do not at present require to be licensed but will be so required under the Meat Foodstuffs Order 1941 from a date to be announced

Answering a question to the Minister of Health, Miss F **Horsbrugh** said that under the Food and Drugs Act 1938 the business of slaughtering animals, including horses, for human consumption, requires a licence granted by the local authority Further, it is an offence not only to sell, but to have in possession for sale, or to consign to any person for that purpose, any food, including horseflesh, intended for but unfit for human consumption Officers of local authorities have full powers to inspect such food and if necessary seize it with a view to condemnation

Milk for the Elderly

Sir **Frank Sanderson** asked the parliamentary secretary to the Ministry of Food whether he was aware of the hardship which was being experienced by elderly people, say over 75 years of age, in not being able to secure adequate milk supplies, and would he consider granting them an extra ration on a basis equivalent to the increase to be granted to young children —Major **Lloyd George** replied The comparative needs of different groups of people for liquid milk have been most carefully considered in conjunction with the food rationing (special diets) advisory committee of the Medical Research Council In view of the supply position it has been possible to grant priority of supply only to those whose needs are greatest, and the ministry's expert advisers do not put elderly people within this category

American Doctors

Sir **Ernest Graham Little** asked the Minister of Health to what services the medical practitioners, who were coming from the United States of America to take up work in this country, were being allotted to what body their original selection and ultimate distribution was entrusted, what remuneration was offered to them, and what remission of the rate of income tax imposed on British subjects was accorded to these American practitioners on the salaries paid to them in this country in respect of such service —Mr **Brown** replied The doctors referred to are being allotted either to the E M S or to the R A M C according to their own choice The selection of the doctors, so far as their professional qualifications are concerned, is carried out in America through the National Research Council, the American Medical Association and other professional bodies Medical examinations and interviews are arranged in America on behalf of H M Government Doctors who choose the E M S are posted to hospitals by the director general The remuneration offered to them is the salary of medical officer in the E M S —£550 a year plus board and lodging, or £100 a year in lieu thereof I understand that this remuneration is subject to British income tax in the ordinary way, but the amount of the tax is repaid to the doctors by my department, subject to the deduction of a sum equivalent to American income tax at current rates The distribution and remuneration of those doctors who elect to serve in the R A M C are matters for the Secretary of State for War

National Medical Register

Mr T E **Groves** asked the Minister what efforts, apart from an announcement in the *British Medical Journal*, the Central Medical War Committee had made to maintain the national register of the medical profession up to date, and why had not other medical organisations and journals been approached to assist —Mr **Brown** replied I am informed that the Committee obtains information for the maintena of the register from the local medical war committees, pitals and various other sources, and that it avails itself the assistance of such other medical organisations channels of communication as seem most likely to be eff

Home Guard Medical Officers

Mr **Groves** asked the Secretary of State for War w he would raise the age of enlistment for Home Guard me officers, since over age doctors who were still in practice necessarily be employed but could not benefit from cl of instruction, &c, unless they were actually enrolled in Home Guard —Captain H D R **Margesson** replied C of this kind are considered on their merits In general upper age limit is not strictly enforced for practitioners ing to enrol as medical officers in the Home Guard, pro that they are fit

Mr **Groves** Was it the considered policy of his ment that zone medical advisers of the Home Guard be appointed from among the whole time servants local authorities, and, if so, would he give an as that such officers had sufficient time for the duties would be imposed upon them ?—Captain **Margesson** avoid undue interference with the medical organisation of locality, no medical practitioner may be enrolled in Home Guard unless previous permission has been given the local medical war committee, which is aware of the fessional commitments of practitioners in its areas T should ensure that Home Guard appointments are not sistent with the fulfilment of a practitioner's existing ob tions

Medical Board Delays

Sir **Irving Albery** asked the minister if he was aware the long delay which occurred in obtaining a medical bo and subsequent discharge, by men on home stations w were believed to be incapacitated for further service Captain **Margesson** replied Steps have recently been ta to simplify and accelerate the procedure for bringing sold before a medical board and carrying out their discharge order to prevent delays of this kind Revised were issued on Nov 1

Sir **Irving Albery** Will the minister consider whether would not be better to send these men to the depots ? Captain **Margesson** That is the effect of the new instru

Hospital Accommodation at Slough

Sir **Ernest Graham Little** asked the Minister Health whether he was aware that there was no gen hospital nearer to Slough than Windsor, where the acc modation was overtaxed, and whether, in view of special circumstances, he would authorise the reception civilian cases by the E M S hospitals in Slough, where th was unused accommodation which the medical profession Slough urgently needed Mr **Brown** replied I am aw that there has been considerable pressure on the beds at th general hospital at Windsor, and I arranged facilities time ago for reducing the waiting list by transfer of cases emergency hospitals within reach of the area It rests wi the hospital to take full advantage of those arra The emergency hospital at Slough is in the county council' institution While it is essential to keep a certain num of beds available there for air raid casualties and oth emergency cases, it has always been made clear that th council can and should admit in the normal way cases needin urgent hospital treatment who cannot get it elsewhere

Spectacles for the Troops

Answering a question, Captain **Margesson** said that eve soldier who requires spectacles is supplied with two pairs that it should rarely happen that he is not in possession of a least one serviceable pair There is now no delay in th initial supply of spectacles to soldiers, and adequate arrangements have also been made for the replacement of damage or lost spectacles in any theatre of war where British troop are serving

Medical Referee for Notts

Mr **Bernard Taylor** asked the Home Secretary on whose advice Dr F S Airey, of Leicester, was appointed medical referee for Nottinghamshire, and was he aware that there was a decided objection by the Nottinghamshire miners attending Leicester —Mr **Herbert Morrison** replied Following a decision to appoint a specialist medical referee for cases of dermatitis arising in this area efforts were made in nsultation with the county court judge, to obtain the ser- ces of a suitable dermatologist in Nottingham but without ccess The vacancy was then advertised Dr Airey was e only applicant, and on the recommendation of my medical lvisers he was appointed I appreciate that a medical referee t Nottingham would be more convenient for the Nottingham- ure miners, but there does not appear to be a suitable ermatologist there who would be willing to accept the ppointment at the present time

Fifth Valuation of Approved Societies

In reply to a question, Mr BROWN stated that a short eport by the Government Actuary, incorporating such atistics of the results of the fifth valuation of approved ocieties as it is practicable to furnish in present circum- tances, will be available early next year

Public Health

Damaged Food

IT was only comparatively late in the last war that ttention was directed to the urgent need for adequate teps to prevent food spoilage and to conserve what was tilisable At that time it was possible to visit many ports and find large stacks of tinned sweetened milk set aside as unsound and often they were all of one brand The history of that brand is interesting. It came from the United States and in their endeavour to supply the English market some plants were put into operation and run not by experienced packers, but by people comparatively new to the trade In this case the promoters were unfortunate, for the site selected for the new factory was a disused brewery Since the commonest agent causing sweetened condensed milk to become "blown" is yeast fermentation and since a brewery normally swarms with yeasts, it was not unnatural that a large proportion of each consignment became unsound But it had its serious side—it was bad economy to use limited shipping space for food which was condemned as soon as it reached this country It is important that we should not make similar mistakes in this war, when the problem of shipping space looms even larger It is disquieting to read in the *Evening Standard* of Nov 13 that the Southwark authority applied for the destruction of 38 cwt of cooked pressed meat from Eire on the ground that it was unfit for human food because it was infected Mr Bernard Campion the magistrate, said this was the third lot of meat from Eire which he had been asked to condemn, while the medical officer of health, Dr William Stott mentioned that there were large quantities of this meat being imported No precise bacteriological information is given as to the nature of the unsoundness but the whole of this particular consignment is said to have gone putrid 24 hours after being taken out of cold store Probably there was no evidence of specific contamination with food-poisoning bacilli, but inadequate care resulted in putrefaction Apart, however, from bacteriological considerations it is obvious, particularly in these days, that practical measures must be applied to preserve our food, whether it is imported or whether it is produced and prepared in this country The present system of centralised slaughter-houses was devised and operated from the point of view of distribution, the requirements of adequate supervision and inspection were secondary considerations Those responsible for meat supervision were not consulted as to the suitability of these centralised slaughter-houses or even as to whether they were the best available in the area In fact a number of them are most unsuitable although improvements have been made Being placed in one local area the whole of the burden of meat inspection is thrown on the food inspector (almost always the sanitary inspector) of often quite a small town, without regard either to his experience in meat inspection or the multiplicity of his other duties No provision has been made for him to be assisted by the other food inspectors in the area served although voluntary assistance has been given in some cases Some premises are so unsatisfactory that adequate supervision is particularly difficult There is evidence from various sources that the number of food-poisoning outbreaks has increased All this, with revelations such as those at Southwark suggests that the Government needs to pay more attention both to the control over food and to the application of all practicable measures to prevent food becoming unsound If food is found unfit for human consumption, there is still the possibility that it could be heat-treated and made available for manufacturing purposes or fed to animals These problems seem to fall within the purview of two ministries—of Health and of Food—and possibly they sometimes fall between the two There is plenty of expert advice available if outside help is required As an example of what can be done the following instance may be mentioned A very large consignment of tinned herrings in tomato sauce was imported recently into this country and on inspection a small proportion of the tins were found "blown," while a higher percentage showed the slight unsoundness called in the trade "springers" The question of condemnation arose, but instead the local medical officer of health consulted the county M O H, who with the aid of the county laboratory was able to establish the soundness of all except the definitely blown tins The advice given and taken was to keep the whole consignment for a month and after rejection of the definitely unfit to pass the rest unless the holding disclosed a different state of affairs In this way almost the whole of this large consignment was used without risk

Tuberculosis in Lancashire

Dr G Lissant Cox offers a precis of the work of his department for 1940, but all the records are available for reference In a county population estimated at 1 900,870 there were on the dispensary registers 7533 patients suffering from tuberculosis (4324 pulmonary, 3209 non-pulmonary), and of these 19 9% were children under 15 During the year 1394 new cases of pulmonary tuberculosis were reported an increase of 105 over 1939, and 751 new cases of non-pulmonary tuberculosis 39 less than in 1931 Among young women aged 15-35 there were 386 new notifications of pulmonary tuberculosis (336 in 1938 and 377 in 1939) 1064 persons died from tuberculosis during 1940, giving a rate of 0 55 per 1000 of the population, and this was an increase of 0 01% on the 5-year average

The county has been able to maintain all its beds, the monthly average in occupation being 942 An increasing amount of thoracic surgery is being done and of the 4324 pulmonary patients 978 received some form of surgical treatment During 1940 the tuberculosis officers have examined and X rayed 656 recruits referred to them by the civilian medical boards and the council have agreed that recruits for the women's auxiliary services may have the same facilities

Infectious Disease in England and Wales

WEEK ENDED NOV 15

Notifications —The following cases of infectious disease were notified during the week smallpox, 0, scarlet fever, 1352 whooping-cough 2066 diphtheria 1043, paratyphoid, 30, typhoid 9, measles (excluding rubella), 671, pneumonia (primary or influenzal) 997, puerperal pyrexia 136, cerebrospinal fever 104, poliomyelitis, 21, polio-encephalitis 1, encephalitis lethargica, 5, dysentery, 204, ophthalmia neonatorum 78 No case of cholera plague or typhus fever was notified during the week

The number of civilian and service sick in the Infectious Hospitals of the London County Council on Nov 12 was 1307 including scarlet fever, 181 diphtheria 250 measles 38 whooping-cough 475 enteritis 43 chicken pox 40 erysipelas 24 mumps 5 poliomyelitis 8 dysentery 25 cerebrospinal fever 10 puerperal sepsis 11 enteric fevers 34 other diseases (non infectious) 87 not yet diagnosed 76

Deaths —In 126 great towns there were no deaths from enteric fevers or scarlet fever, 2 (0) from measles, 8 (2) from whooping-cough, 43 (1) from diphtheria, 37 (3) from diarrhœa and enteritis under 2 years, and 38 (4) from influenza The figures in parentheses are those for London itself

There were 12 deaths from diphtheria at Liverpool 4 at Birmingham and 3 at Sheffield Manchester reported 5 deaths from influenza

The number of stillbirths notified during the week was 195 (corresponding to a rate of 38 per thousand total births), including 22 in London

The M B E has been awarded to Lieutenant G D Eccles M B Home Guard (Dawlish), for "conspicuous gallantry in carrying out hazardous work in a very brave manner

Letters to the Editor

HYPERTENSION

SIR,—The article by Dr Richardson and Dr Smart in your issue of Nov 15 is of great interest in that it records two further examples of fall in blood-pressure following the removal of a diseased kidney It would however be wrong not to challenge the assertion in their penultimate paragraph that "all cases of chronic hypertension should have a complete urological investigation" In accord with contemporary practice we may perhaps promote Hypertension to the rank of Captain of the Men of Death It is an extremely grave, common and intractable disease and any clue as to a means of treatment, requires careful examination The recent work of experimental pathologists, beginning with Goldblatt and his collaborators and reaching a culmination in the recent work of Byrom and Wilson, at last throws some light on a situation of tragic obscurity But if this work demonstrates that hypertension can be produced by reducing the renal circulation through one or both kidneys it in no way suggests that it is usually produced by a unilateral lesion We know full well that in the vast majority of cases any demonstrable disease is bilateral and that in an even greater number nothing at all can be shown to be wrong with the kidneys during life

I would submit that a complete urological investigation of such cases would be a waste of time and money for a horde of unfortunate patients calling for very different treatment In point of fact each of the cases described in the article had localising signs from the very outset

Middlesex Hospital, W 1 T IZOD BENNETT

COMPRESSED LIMB RENAL FAILURE

SIR,—In conformity with modern thought—which shows little sign of regressing, of considering any other view—the renal failure following limb compression in bombed dwellings has been imputed to a "toxin" derived from the damaged part A better, a more reasonable, a more helpful view is that the renal failure begins, advances and ends as the result of an "active congestion of the kidney" (Maitland, A I *Brit med J.* 1941, 1, 570, *Lancet*, 1941, 2, 446)—the cause of which, however, is arterial in origin Induced by reflexes elicited during the burial period—the Loven reflex, the skin response to cold, and reflexes arising from pain and fear—it is advanced by the transfusion given to combat shock Indeed, so marked is the effect of tranfusion on the kidney in these cases that it almost seems that the "nephrotoxin" must exist in the blood or plasma administered to the patient But on the one hand cases of shock, unassociated with limb compression, treated by transfusion, do not develop renal failure (Bywaters, E G L and Beall, D *Brit med J* 1941, 1, 432), on the other hand a case of limb compression treated by infusion to induce diuresis, shock being absent, resulted in anuria (Mayon-White, R and Solandt, O M *Brit med J* 1941, 1, 434) It is thus clear how the transfused blood acts, it acts mechanically, increasing the mass of the circulating blood The signs of shock disappear, but the arterial congestion of the kidney, diminished by the state of shock, is reinforced, the patient dying of renal failure

How explain the shock? Recently I wrote that "the idea that shock is due to a toxin is a myth" Consider the evidence pointing the other way—it is colossal But if shock, in these or in any other cases, is due to a "toxin," we must suppose that the blood transfused, since it cures the patient of shock, must contain an antitoxin to shock—which is absurd The blood transfused, as we have seen, acts purely mechanically, it is thus not surprising to find that mechanical measures, other than that of increasing the blood mass, can combat shock—e g, placing the patient in the Trendelenburg position A patient of mine, of a different sort, with a falling blood-pressure was placed in the Trendelenburg position, by raising on chairs the legs at the bottom of the bed In spite of that, the patient got worse, the systolic pressure in the brachial artery fell below 40 mm Hg—the reading was confirmed by the resident medical officer who said "we must do something" We did do something we raised the foot-end of the bed on lockers, which with a small rectal saline resulted in complete recovery

Shock in these bombing cases is predisposed to by the dehydration, and precipitated by the œdema, watery parts of the blood exude into the compressed and damaged limb, increasing its volume but by so much diminishing the volume of the circulating blood After admission, the placing of the patient in a warm bed and the application of heat, by attracting blood to the skin, facilitate the appearance of shock Shock, which must diminish an arterial congestion of the kidneys, as a rule does not last long enough to relieve the renal block which the arterial congestion has caused, with a praiseworthy zeal it has been met with immediate transfusion—to the undoing of the patient In the same way fluids have been pressed when they should have been restricted Something seems wrong It is, I think, that laboratory experiments, thought to mimic nature, are often a gross caricature, and that the life of man is regarded as a series of biochemical reactions rather than as a sequence of biophysical events

Rugby R H PARAMORE

BLAST INJURY OF THE LUNGS

SIR,—Dr Osborn states that no real pathological or clinical distinction has been shown to exist between cases of pulmonary concussion from (*a*) mechanical causes such as road accidents, (*b*) bomb explosions, and (*c*) depth charges This last is outside our experience Clinically, our cases did not resemble cases of mechanical injury There was not the slightest risk of overlooking the lung damage, which Dr Osborn says may easily happen in cases of mechanical injury Even the milder cases showed symptoms and physical signs which no-one with any experience of chest conditions could miss In almost all Dr Osborn's cases blast and mechanical injury appear to have been associated, whereas it is our contention that the effects of blast and mechanical injury should be studied separately at present until it can be shown that they are identical

The translation of Dr Osborn's term "predisposition" into the phrase that blast lesions are "best marked in the phrenico-costal sinus," may not have been a happy one, and we regret it if we have misinterpreted him In our experience a phrenico-costal sinus pneumonia, separate from one involving the bulk of the lower lobe, developed only once (case 3, fig II) In addition this man had lesions diffused through the whole of both lung fields This patient had had severe abdominal blast Only one other case with severe abdominal blast developed pneumonia (case 7), and this involved the whole lower lobe Five other cases without abdominal symptoms developed pneumonia involving the whole lower lobe In four severe cases, and in all the milder ones, there was no evidence of phrenico-costal pneumonia and no grounds were found for directing special attention to it

London Chest Hospital, E 2 S ROODHOUSE GLOYNE

A STATE MEDICAL SERVICE

SIR,—Those who put forward schemes for the improvement of medical practice are performing useful work but must be prepared for criticism Quite apart from the vested interests of medicine, from which quarter Dr Thompson appears to expect opposition, it seems likely that many of his colleagues in the public-health service are hoping that he will reconsider the ideas he has put forward in your issue of Nov 15 (p 613) Although the framework of the scheme does not greatly differ from others which have already been put forward, it proposes to deal a death blow to the present preventive health services of the local authorities Dr Thompson's Utopia is to emerge from a national service of insurance practitioners who will take over the work of the maternity and child-welfare and school medical services which in his own words "would disappear" From the chief medical officer of a welfare authority this is indeed a surprising suggestion and it is difficult to believe that its implications have been realised

Since the maternity and child-welfare movement began enormous strides have been made in the care of mothers and young children The work done by the welfare councils in the past has been followed by a dramatic fall in the infant death-rate and later in the maternal mortality figures But the supervision of infant feeding and child care generally demands a knowledge of pædianics while the prenatal clinic is of little use if the doctor s not a competent obstetrician These are specialist obs, and while I fully appreciate the excellent work of N H I practitioners it must be questioned whether they would be willing to take over the educative and preventive work in these subjects in addition to their clinical duties In any case they would not have the time, and the urgent calls of the sick would have to take precedence over the routine examination of the presumably healthy

No form of state service would be possible without the inclusion of the general practitioner, and it is for us all to ensure that the status and working conditions proposed will be suitable and calculated to maintain the high traditions of the profession But in any national scheme it is hardly conceivable that the educational side of preventive medicine—the maternity and child-welfare and school medical services—should not form the basis of all medical work The framework of these services now in existence is perfectly satisfactory , their efficiency depends on their degree of development and on the quality of the personnel Some areas are still behind others but that is no reason why their services should not be improved Surely the foxes with no tails might try to grow them instead of advising others to cut theirs off

Welbeck Street, W 1 VIOLET RUSSELL

LIGATION OF PATENT DUCTUS ARTERIOSUS

SIR,—I have read with interest Mr Mulvany and Sir Maurice Cassidy's comments on our article It remains clear, however, that (1) in the two cases reported by us the ductus arteriosus was patent and infected, (2) neither before, during or after operation was there any evidence of the presence of any other congenital cardiac defect, (3) the patients have remained in good health and without symptoms for over a year now, (4) no other treatment of infected endocarditis or arteritis has in my experience yielded two successive cures in two successive cases, and (5) the percentage of spontaneous cure is less than 1%

I agree with Sir Maurice that it is yet to be seen whether ligation could be justified as a prophylactic measure, for even after ligation a local dimple must persist at the site of the tied ductus, and this might provide a nidus for future infection But I do not agree that the fact that spontaneous remissions may occur is sufficient to justify us in withholding from a patient a proved therapeutic measure which may have risk attached to it The risk of the measure must be balanced against the risk of non-intervention, and the chances of remission in infected congenital cardiac defect are very minute

Queen Anne Street, W 1 GEOFFREY BOURNE

WHEN TO TIE THE CORD

SIR,—Is there not a tendency to stray from essentials in the consideration of this matter? As far as I am aware, Nature made no provision for adventitious aid in arresting the circulation through the cord This phenomenon occurs spontaneously, and it does not seem unreasonable to take the cessation of pulsation in the cord as the sign that the placental circulation has in fact been arrested This arrest may actually be established before all pulsation ceases, as the only fact that we are entitled to assume from the presence of pulsation is that the vessels are patent between the heart and the point at which the pulsation is felt This consideration does not, in my opinion, affect the main issue

Accepting the evidence for oxygen lack being the prime stimulus to respiration in the newborn infant, is it too much to assume that this lack is brought about by normal physiological mechanisms, and should not depend on the arbitrary application of some external obstruction to the vessels of the cord? It is, after all, a commonplace of practical observation that in the vast majority of normal deliveries the child starts to breathe shortly after birth, and before any outside mechanical interference with the cord has been undertaken It seems to me that as labour proceeds a time must come when the placenta is unable to adapt itself to the changed size and shape of the uterine placental site, consequent on the reduction in size of the uterus This must lead to a progressive separation of the placenta that would be sufficient to initiate the requisite oxygen lack

Dr Chisholm has suggested that the newborn baby is in danger of bleeding into its own placenta and possibly from placental tears Some light on these risks might be obtained from records of precipitate births involving spontaneous rupture of the cord and the consequent possibility of hæmorrhage from the main umbilical vessels In any event it would seem that to stress the propelling action of the heart as the sole motive power in the placental circulation after birth is to neglect entirely the suction effect that must be exerted by the increase of negative pressure in the thorax that accompanies the child's first inspiratory effort An immediate ligature of the cord, as advised by Dr Chisholm, may well prevent this suction mechanism from coming into play, and for this reason and in view of the considerations outlined above I would end with a strong plea on behalf of those whose practice it is to defer such an operation until at least " the cord has ceased pulsating "

Baldock, Herts J H MOYNIHAN

IMMUNISATION AGAINST TETANUS

SIR,—In your last issue Dr Evans makes a comparison between the antitoxic response following two inoculations of tetanus toxoid and that noted subsequent to a third injection administered 10 months after the original doses It is noted that there is a rapid, and in many instances a profound, increase in antitoxic titre as a result of this further stimulus of the immunising mechanism In consequence of this observation it is suggested that it might be worth the added administrative difficulties to give this third injection

It may be of interest to note that some time prior to my relinquishing the direction of the pathological services of the Army five months ago an instruction was issued to the effect that a third injection of tetanus toxoid was to be given 12 months after the original inoculations As, no doubt, you are aware active immunisation against tetanus by the two dose method was introduced as a routine procedure in 1938 in the British Army Such information as we have at present lends colour to the view that it has had an influence on the prevention of tetanus amongst the battle casualties sustained in the Belgian campaign It is probable that the third injection now given will so increase the antitoxic level that this protection will still further be enhanced

The present heavy fighting in the Western Desert should yield some data relevant to this method of prophylaxis Information on this subject will, therefore, be awaited with interest

Walton on Thames H MARRIAN PERRY

SIR,—In your opportune leading article of Nov 22 you do not mention that simultaneous passive immunisation with antitoxin and active immunisation with tetanus toxoid is provided for in United States Army and Marine orders The British Army gives two doses of toxoid six weeks apart A wounded British soldier will at once receive one emergency dose of antitoxin If his record then shows that he was previously immunised, nothing further will be done, but if he is not already actively immunised he will get, I understand, three weekly injections of antitoxin as at the end of the last war The U S Army gives—not only to those who so opt, as in the British Army, but to all personnel—an " initial immunisation " of three doses of toxoid three weeks apart followed by a " stimulating dose " of 1 ml at the end of the first year or prior to departure for war, if the departure occurs more than six months after the first yearly dose (*War Medicine*, May 1941, p 426) An " emergency stimulating immunisation " is given for battle wounds or secondary operations Antitoxin is not used except for the treatment of clinical tetanus If those who have not been previously immunised are wounded they receive a single dose of antitoxin and a dose of toxoid plus two further doses as in initial immunisation The U S Army and the U S Marines bestow their affections where they will—one prefers the air-cooled airplane engine, the other the liquid-cooled The Army uses toxoid, the Marines use the insoluble alum-precipitated tetanus toxoid, and give to all personnel two doses of alum-precipitated toxoid four weeks apart A further 1 ml is injected about a year later or in the event of a severe battle or non-battle wound or burn, or if a secondary operation becomes necessary Antitoxin is used for the treatment of clinical tetanus or for inade-

BLAST INJURY OF THE LUNGS

SIR —Dr Osborn states that no real pathological or clinical distinction has been shown to exist between cases of pulmonary concussion from (*a*) mechanical causes such as road accidents, (*b*) bomb explosions, and (*c*) depth charges This last is outside our experience Clinically, our cases did not resemble cases of mechanical injury There was not the slightest risk of overlooking the lung damage, which Dr Osborn says may easily happen in cases of mechanical injury Even the milder cases showed symptoms and physical signs which no one with any experience of chest conditions could miss In almost all Dr Osborn's cases blast and mechanical injury appear to have been associated, whereas it is our contention that the effects of blast and mechanical injury should be studied separately at present until it can be shown that they are identical

The translation of Dr Osborn's term "predisposition" into the phrase that blast lesions are "best marked in the phrenico-costal sinus," may not have been a happy one, and we regret it if we have misinterpreted him In our experience a phrenico-costal sinus pneumonia, separate from one involving the bulk of the lower lobe, developed only once (case 3, fig II) In addition this man had lesions diffused through the whole of both lung fields This patient had had severe abdominal blast Only one other case with severe abdominal blast developed pneumonia (case 7), and this involved the whole lower lobe Five other cases without abdominal symptoms developed pneumonia involving the whole lower lobe In four severe cases, and in all the milder ones, there was no evidence of phrenico-costal pneumonia and no grounds were found for directing special attention to it

London Chest Hospital, E 2 S Roodhouse Gloyne

A STATE MEDICAL SERVICE

SIR,—Those who put forward schemes for the improvement of medical practice are performing useful work but must be prepared for criticism Quite apart from the vested interests of medicine, from which quarter Dr Thompson appears to expect opposition, it seems likely that many of his colleagues in the public-health service are hoping that he will reconsider the ideas he has put forward in your issue of Nov 15 (p 613) Although the framework of the scheme does not greatly differ from others which have already been put forward, it proposes to deal a death blow to the present preventive health services of the local authorities Dr Thompson's Utopia is to emerge from a national service of insurance practitioners who will take over the work of the maternity and child-welfare and school medical services which in his own words "would disappear" From the chief medical officer of a welfare authority this is indeed a surprising suggestion and it is difficult to believe that its implications have been realised

Since the maternity and child-welfare movement began enormous strides have been made in the care of mothers and young children The work done by the welfare councils in the past has been followed by a dramatic fall in the infant death-rate and later in the maternal mortality figures But the supervision of infant feeding and child care generally demands a knowledge of pædia-

Hospital Saving Association

Despite war-time difficulties the number of contributors to this association on July 31, 1941, was almost 1,690,000 and the income for the year was £970,000 This year the association has paid the London hospitals *9s* for each inpatient day and *7s 6d* for each outpatient, except when these figures exceeded the 1939 statistical cost But fewer of the association's contributors have been ill, only 3% compared with 6% in 1938-39, while the outpatients had fallen from 20 to 11 2%

Naval Honours

The D S C has been awarded, for courage and resolution in operations in Mediterranean waters, to Temp Surgeon Lieutenant E R L Davies, M R C S, R N V R, H M S *Manchester*, Temp Surgeon Lieutenant C J Vaughan, M B Dubl, R N V R, H M S *Forster*, and Temp Surgeon Lieutenant E J Yates, M B Manc, R N V R, H M S *Fearless*

Harben Lectures

These lectures, which are delivered under the auspices of the Royal Institute of Public Health and Hygiene, will this year be held in Canada On Dec 1, 2, and 3, at 4 P M, E V McCollum, Sc D, professor of nutrition at Johns Hopkins University, will give them at the University of Toronto, and he has chosen as his subject nutritional science and public health

Pituitary Extracts

The supplies of pituitary extract issued by the Ministry of Health for use in E M S hospitals and first aid posts carry the expiry date of Oct 26, 1941 But the Medical Research Council have tested samples and report that where supplies have been kept under ordinary conditions at normal room temperature they may be used with safety for a further twelve months

Anglo-Soviet Medical Committee

The Anglo Soviet Medical Committee appeals to all who have any surgical instruments which they can spare to send them as soon as possible to the secretary of the Joint Committee for Soviet Aid, 171 St Stephen's House, Cannon Row, Bridge Street, London, S W 1 The need is urgent, for the manufacturers can supply only a limited number Instruments which require to be re plated or repaired will be accepted with gratitude and will be restored to good condition before being forwarded to the U S S R

Among the instruments wanted at once are

Artery forceps of every description
Record syringes and needles (international standard pattern)
Needles of all kinds (including intravenous, blood transfusion, hypodermic and spinal)
Scissors of every description
Towel clips
Dissecting forceps
Aural forceps
Bullet or swab forceps
Aneurysm needles
Surgical needle holders
Bone forceps
Scalpels and amputation knives
Plaster cutters
Tracheotomy tubes
Abdominal retractors
Volkmann retractors
Sterilisers and autoclaves
Dental instruments

Dusting Powder for Babies

The Board of Trade in consultation with the Ministry of Health have agreed to allow manufacturers of toilet preparations to supply dusting powder for babies under the name of "baby powder," without the addition of any other words It must be sold as packed by the manufacturers and must not contain perfume, essential oil or colouring matter It must be composed of the silicates of magnesia and alumina and may also contain a small proportion of boric acid. The powder will be distributed only to hospitals, medical practitioners and registered pharmacists and may be supplied only to people who really need it

Communal Meals in Stirlingshire

On Nov 14 Mr Thomas Johnston, M P, Secretary of State, opened the fourth feeding centre for the county at Stirling Centres are already open at Falkirk, Kilsyth and Grangemouth, and almost 12,000 meals a week are served to school children The Stirling centre will be able to serve every day 3000 meals to children and 3000 meals to adults In a short time Stirlingshire will have seven centres with a daily output of 10,400 meals for school children and 9400 for adults Hot meals will be distributed by insulated containers to all schools in the county and to selected centres where there is likely to be a demand, and the director of education for the county, who is in charge of these feeding arrangements, hopes to be able to supply the mining community in districts where no facilities for pit head canteens exist

Notes, Comments and Abstracts

NURSES CONSIDER THEIR PROFESSION

THE inaugural meeting of the Nursing Reconstruction Committee, under the chairmanship of Lord Horder, was held on Nov 24 at the Royal College of Nursing This body is composed half of delegates appointed by the college and representing different aspects of nursing, and half of delegates from kindred associations including the British Medical Association, the Society of Medical Officers of Health, the Nuffield Trust, King Edward's Hospital Fund for London (Nursing Recruitment Centre), Local Authorities' Nursing Services Joint Committee, the Medical Women's Federation, the British Federation of Business and Professional Women the National Association of Administrators of Local Government Establishments, the Trades Union Congress, the Incorporated Association of Hospital Officers, the Hospital Matrons Association, the Queen's Institute of District Nursing and many others The delegates are to consider ways and means of implementing the recommendations of the Athlone Committee and to recommend such further adjustments as the present situation and post-war reconstruction may demand It is stimulating to see this extremely practical approach. It is easy—or relatively easy—to make recommendations for amending the nursing profession, since many defects in the terms of service are as widely known as they are of long standing But to settle down to convert opinion into action is a different and worthier task In welcoming the delegates Lord Horder reminded them that even in the short interval since 1939, when the interim report of the Athlone Committee appeared, important developments had occurred, among them the setting up of a division of nursing at the Ministry of Health, but there was much to be done He pointed out that recruitment falls short of demand, education of nurses is cramped by the economic needs of the training institutions, prospects are too poor to attract women of ability, and conditions of service are not everywhere what they should be The profession looks for the establishment of negotiating machinery on the lines of the Whitley Councils to bring such conditions into line The new committee has a great work before it and we wish it well

TUBERCULOSIS IN SOUTH AMERICA

ELEVEN of the Spanish-American countries took part in the fifth Pan-american Congress for tuberculosis held at Buenos Aires and Cordoba at the end of last year In his presidential address Prof G Sayago said that these new countries had a common geographical, racial, economical and social background, and the statistics submitted to the congress showed that at any rate in their rural districts they were faced with common problems in the control of tuberculosis In the larger cities of South America the problems connected with the disease were more comparable to those of the older nations In the towns the incidence of the disease is high and as rural districts become industrialised they are exposed to infection, its spread among children is disquieting But the congress did not consider that heredity was an important factor and infection by the placenta was rare Non-pulmonary tuberculosis does not show the same clinical picture as in Europe, for surprisingly often it is associated with active or incipient pulmonary infections These patients should be treated in special sections of the hospitals The next congress will be held in Habana in 1943 and the subjects for discussion will include the value of BCG vaccination, initial stages of tuberculous infections, and the treatment of pulmonary cavities

At the congress it was emphasised that the number of beds available in South America was insufficient for the number of tuberculous patients To implement her share of the campaign against the disease the Argentine Government has set up a national committee, working under the department of health, which will coordinate the work of sanatoriums and laboratories receiving grants from the government, and establish new sanatoriums in rural districts in the interior According to official figures there are only 5000 beds available in the republic and these can accommodate only a third of the patients, but the results achieved so far have been quately immunised men, to whom a dose of tetanus alum toxoid is given at the same time, and the second dose a month later The American Army and Navy thus both aim at passive plus active immunity at the same time The factors are not the same as those described in the *British Medical Journal* of Nov 20 (p 717) by a group of investigators studying the immunology of diphtheria If antitoxin and toxoid are given at the same time, the toxoid cannot act much while the antitoxin is present Until it is got rid of there is a dangerous interval, the individual is exposed to infection if in contact with a carrier before the toxoid can act and produce active immunity But in tetanus the man is not exposed during this time to external infection

In passing, I would guess that the excellent American *War Medicine* has not yet gained full currency here Among other items, a recent number tells that the American fighting man will have his blood-group marked on his card, as in the Australasian Army

X

SCIENCE OR ART?

SIR,—In your issue of Nov 15 Professor Plesch stated that " we have lost confidence in our intuitive abilities and do not use or rely on our five senses sufficiently, this is regrettable because medicine must always remain an art to which science is only the servant " He then goes on to state that " our judgment must depend partly on imaginative intuition, and we can only pass on to the student the method of making the bricks from which he must build the diagnosis " I feel myself that we have rightly lost confidence in our intuitive abilities Intuition is subjective and should be distrusted by the scientific mind I disagree that medicine must always remain an art to which science is only the servant It would be better both for the practitioners of medicine and those practised on that it should be primarily a science and secondarily an art For some thousands of years medicine was an art, it was only when it tended to become a science that it began to command respect from intelligent minds A teacher can pass on to his students a scientific attitude of mind which will ultimately benefit medicine and benefit his patients

Gorseinon, Swansea G E DONOVAN

PARADOXICAL CEREBRAL EMBOLISM

SIR,—I am interested in the case recorded by Dr Porter in your last issue but venture to dispute his diagnosis It seems to me much more probable that the case was one of cerebral thrombophlebitis I have published a comparable case (*Brain* 1937, 60, 531) in which following thrombophlebitis in the left leg symptoms of increased intracranial pressure developed which were presumed to be due to thrombosis of the superior longitudinal sinus Thrombophlebitis even if widespread is not necessarily accompanied by fever, nor is the lung often involved when thrombophlebitis arising in the lower part of the body subsequently affects the cerebral veins Indeed in the puerperal cases pulmonary involvement appears to be the exception rather than the rule The spread in such cases is probably by mural thrombophlebitis, along the intravertebral veins, as Purdon Martin has suggested (*Brit med J* 1941, 2, 537) The experimental work of Batson (*Ann Surg* 1940, 12, 138) upon which this suggestion was based strengthens the belief which I have held for some time that many cases of hemiplegia which in the past have been attributed to arterial embolism, thrombosis or hæmorrhage, have in reality been due to cerebral thrombophlebitis I would add that the rapidity of recovery in Dr Porter's case is an additional argument in favour of the diagnosis of cerebral thrombophlebitis as opposed to cerebral embolism

Oxford C P SYMONDS

LONDON HOSPITAL—An award of the Hutchinson triennial prize will be made in 1944 for a dissertation on the investigation and treatment of sciatic pain Candidates must be full students of the hospital, but not necessarily of the medical college, and they must have registered as students not more than ten years ago Dissertations should be submitted to the secretary of the hospital medical council by Oct. 31, 1944.

Medical News

Royal Society

The King has approved the recommendations made council of this society to award a royal medal to Prof Kennaway, F R S, for his investigations on prod cancer by synthetic substances

The Copley medal has also been awarded to Sir Lewis, F R S, for his experimental researches, in the and the laboratory, on the heart and the circulation and disorders, and the Davy medal to Dr H D Dakin, F for his work as a pioneer in biochemical research and es because of his fundamental contributions to the study of mediate metabolisms

Royal Society of Medicine

There will be a general meeting of the fellows of this on Tuesday, Dec. 2, at 3 30 P M On Dec. 3, at 2 45 P the section of history of medicine, Mr Charles F R I B A, will read a paper on hospital building present and future At 2 30 P M, on the same day, at section of surgery, Dr E G L Bywaters and Mr Belsey will open a discussion on the effects on the kidney trauma to parts other than the urinary tract including syndrome The section of laryngology will meet at 10 A M, on Dec 5, to discuss the effects of flying on the nose ear The opening papers will be read by Wing J F Simpson, Group-Captain E D D Dickson, Leader D B Fry, Squadron-Leader J E McGibbon Squadron-Leader R H Winfield At 2 30 P M, on the day, Dr Z Mennell and Dr Ronald Jarman will open a cussion at the section of anæsthetics on the present position ether

Health Films in America

The American Film Center, 45, Rockefeller Plaza, N York, has opened a section on films in health education medicine, to which the Rockefeller foundation has promised three year grant Dr Adolf Nichtenhauser, who is in cha of the section, has been working on educational cinemat graphy for many years and before joining the centre he wa on the staff of the National Tuberculosis Association and New York Tuberculosis and Health Association The section will be a clearing-house and information centre on use and production of medical films for laymen and It will from time to time publish lists of recommended fil and it will develop a production programme with other agencies

General Practitioners of West Ham

The practitioners of West Ham met on Nov 19, to the necessity for united and sustained action to meet requirements of general practitioners as a body, in view of possible alterations in medical practice due to changing economic conditions Dr Robert Poots was in the chair and 83 doctors were present Dr Poots discussed the raising of the income limit for N H I, the medical care of dependants of members of the Forces, the inadequacy of the recent addition to the N H I capitation fee, the fact that less than 5% of the population earned more than £500 per annum, the effect of increasing income tax burdens on the patient, and how these factors must influence the future of medical practice

Dr Philip Inwald, of Islington, told the meeting what had been done in his district and in the City area in organising the practitioners Dr H C Boyde welcomed the awakening professional interest in social and economic problems affecting medical practice The B M A had suggested it was desirable to form discussion and study groups, to plan future medical progress Dr M J Murphy thought extension and modification of the existing system might give a possible solution Other speakers stressed the need for organisation among general practitioners, to make the wishes of the largest body of medical opinion in the country operative through the leading medical organisations The following resolution, proposed by Dr H A Hannon was carried unanimously, and practitioners from East Ham who were present associated themselves with it

> That a coordinating committee be elected by the general practitioners of West Ham, to link up with other practitioner coördinating committees throughout the country, to watch over the interests of general practitioners by every accepted means to formulate their requirements and forward them to the Medical Planning Commission

A committee of twelve practitioners was elected, instructed to get to work as soon as possible, and report progress at the next meeting, which will be held at an early date

FROSTBITE AND KINDRED ILLS *

RAYMOND GREENE, D M OXFD,
PHYSICIAN, E M S MEDICAL OFFICER TO THE KAMET EXPEDITION
1931 AND EVEREST EXPEDITION 1933

IN time of peace, doctors in England need no knowledge of frostbite The disorder occurs so rarely that many never see it In war it becomes an important military factor, either in its classical form or as the closely allied condition of trench-foot It was a major cause of Napoleon's retreat from Moscow, during which it was described by the surgeon Larrey Should the Germans in Russia be forced to dig in this winter, frostbite may be once more a potent weapon against Russia's enemies Frostbite crippled thousands and killed many in the Balkan wars which immediately preceded the war of 1914–18 but the lessons these cases taught were not learned in time by our own army, despite the efforts of Colonel Max Page (1914), though frostbite is almost always preventable, 84,670 cases occurred in the British Army alone In the week ending Dec 16, 1916, 3104 frostbitten men were admitted to medical units in France and Flanders, and 2521 of these were sent to the base The blizzard of November 1915, caused 15,900 cases in Gallipoli and 998 in Serbia (Mitchell and Smith 1931) Thanks to a few officers of the R A M C and a few commanders who were prepared to accept their advice, there were some units in all theatres of war which suffered little, if at all In the North Russian campaign between September, 1918, and September, 1919, only 48 men were frostbitten A number of cases occurred early in the present war, chiefly in the R A F, but adequate clothing and the heating of aeroplanes soon reduced the incidence to very small figures Nevertheless it is always possible that the British Army may be called upon to fight in conditions of cold and damp and in mountainous countries, where only awareness of the danger and knowledge of its causes and treatment will prevent numerous casualties

In the present war, two other conditions have been recognised which are in close relation to frostbite and trench-foot These are "shelter-foot," often seen among shelter dwellers in London in the winter of 1940–41, and "immersion-foot," commonly observed in those who, after shipwreck, have been forced to spend long periods in water-logged boats

TRUE FROSTBITE

The onset of true frostbite may be sudden or gradual

Sudden frostbite can be studied in comfort by anyone who will take the trouble to squirt ethyl chloride at a friend's nose Dermatologists often produce it by applying a stick of carbon-dioxide snow firmly to the skin In more natural surroundings it develops in exceptionally cold weather, especially in a high wind, or when the exposed skin is brought into contact with cold metal such as an ice-axe, a rifle, a spoon, or the shutter-release of a camera A sting like that of a wasp is usually felt, but sometimes it is painless The skin is white and crystalline If it is observed at once and a warm hand clapped on it, no harm may be done During thawing, a red area appears around the frozen patch which gradually invades it The surroundings gradually return to normal, leaving the patch red and sharply defined Shortly afterwards itching and swelling begin The weal may take many hours to subside, or blistering may follow and even deep gangrene of the skin The flush is due to the opening up of arterioles by the release of H-substance from the damaged area (Lewis and Love 1926)

Gradual frostbite may occur on exposed skin or on well-clothed parts The burning sensation of extreme cold dies away and a pleasant numbness takes its place At this stage the skin may appear normal or may be white and waxy If freezing continues, there is destruction of tissue, blood-vessels give way, œdema and hæmorrhage develop and the vitality of the tissues is destroyed—a course of events which may occasionally be delayed by cold so extreme that the normal contour of the part is preserved as in marble In either form, thawing usually begins before extreme damage has been done, and is itself responsible for the ultimate damage This is the danger period As in sudden freezing, a flush surrounds the frozen area and gradually invades it, till the normal or white skin becomes red Swelling begins when transudation takes place from the damaged vessels In extreme cases whole blood may escape into the tissues and the skin become darkened or purple, blisters then form, the blebs containing straw-coloured fluid or whole blood The true severity depends on the depth of freezing and—more important—the amount of transudation In most cases the damage is only skin deep or involves only the terminal phalanges The appearance is always unduly alarming to the inexperienced A frostbitten hand may have precisely the appearance of a hand in which the main arteries have been blocked by embolism, but arterial pulsation can usually be felt and recovery with but little tissue loss is the rule if sepsis is avoided During the stage of aseptic recovery the unviable tissues become black, hard and painless, and finally—sometimes after weeks—strip off, leaving healed skin beneath The viable but affected tissues gradually recover their normal appearance, but may be hypoæsthetic, or paræsthetic and hyperæsthetic for months Even in a mild case with little or no tissue loss, these disturbances of sensation may occur, and interference with the blood-supply to the nail-bed may result in temporary cessation of nail growth and loss of the old nail some months later Many years may pass before nail growth becomes normal again

TRENCH-FOOT

Larrey was the first to describe trench-foot, which in previous wars has been the most important form of frostbite, he observed that it was less common at extremely low temperatures than when the temperature varied about freezing-point so that the ground though always cold was usually muddy In "The Medical History of the Crimean War" (1858) it is stated that a large proportion of the casualties from this cause occurred when the temperature was above freezing-point It was realised even at that time that in addition to cold other factors were involved, especially damp, constriction and stagnation of the circulation, fatigue, malnutrition and scurvy The author wrote

> The labours and guards of the trenches were those which more especially involved that severe and protracted exposure which was favourable to the occurrence of gangrene The men in the trenches and advanced parallels were so much restricted in their movements and were for the most part so little able, in the presence of a vigilant enemy, to walk about or in any other way to assist the circulation of the blood that they were under the necessity of remaining quiet in the least exposed position, and frequently this position happened to be the bottom of a trench knee deep in mud and water or half-filled with snow

Yet, despite this clear warning, we lost thousands of soldiers in the winters of the last war One contrite colonel, formerly of the R A M C, has told me how at first he forced men with sore feet to return to the trenches He realised his error, but many never did

Trench-foot is almost identical with gradual frostbite There are variations in the mode of onset but the main features are the same numbness followed by swelling and ultimately considerable pain It is important to remember that the feet may be almost free from pain until the boots are removed, when transudation and swelling take place rapidly and the pain may become intense Some men, slightly affected, found that after a few days pain and swelling disappeared, and that they could return to the trenches, only to succumb later to attacks of steadily increasing severity Others were too severely crippled to return

SHELTER-FOOT

In November of last year, Knight (1940) drew attention to swelling of the feet in people who had spent the good, and in Buenos Aires the death-rate from tuberculosis has fallen from 3 14 per thousand in 1938 to 2 79 in 1929

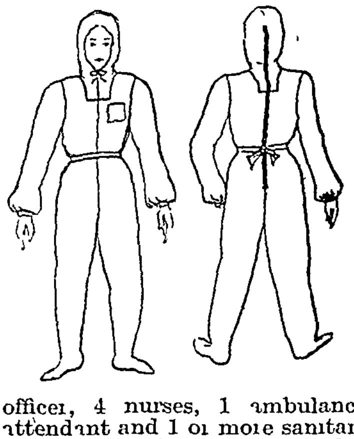
---

* Based on a lecture delivered at the British Postgraduate Medical School on Feb 6, 1941 Reference is occasionally made to experiments to be published fully later conducted with the aid of a grant from the Medical Research Council, to which my thanks are due

The miraculous remedy against tuberculosis has once more been discovered This time by Jesus Pueyo, a Spanish medical student For a time he did research work in the laboratory of microbiology in Buenos Aires and he claims to have discovered a new vaccine, which was announced in the lay press in a sensational manner The minister of the interior urged him to demonstrate its preparation at the National Institute of Bacteriology, but Pueyo made conditions which were unacceptable to the scientists The faculty of medicine also tried to examine the vaccine, but this also came to nothing as Pueyo refuses to permit animal experiments and insists on being allowed to try his vaccine on human beings The use of the vaccine has therefore been forbidden in Argentina and Pueyo has been fined for its unauthorised distribution

TO DEFEAT THE TYPHUS-BEARING LOUSE

THE Ministry of Health (memo 252/Med) puts us on our guard against the possible arrival of louse-borne *typhus in this country in company with refugees*, prisoners of war and returning travellers The body-louse and the head-louse are both probable vectors Diagnosis depends on the sudden onset, high temperature the appearance on the 4th or 5th day of a rash which spares the face, and a torpid or maniacal mental state The Weil-Felix reaction can be obtained by the end of the first week and sometimes earlier A strong reaction in a dilution of 1 in 80 or 1 in 100 obtained by a naked-eye reading, may be taken as positive, and during the later stages of the disease the titre rises to 1 in 1000 or even higher At the other end of the scale, any increase in the agglutinating power of the serum, established by examinations at 2-day intervals, is significant even at a titre of 1 in 50 A vaccine against infection is available but its value in the field has not been tried It is to be used at present only by those working on typhus teams and is to be given in three doses of 1 c cm at weekly intervals If typhus does reach this country it is most liable to break out in crowded areas Several of the large cities have been asked to organise typhus teams each of which is to include the medical officer, 4 nurses, 1 ambulance driver, 1 ambulance attendant and 1 or more sanitary inspectors and trained disinfectors The team should be duplicated so that absentees can be replaced



All team members are to be provided with protective clothing consisting of a one piece garment with a hood fastening down the back, preferably with a Zipper A tape runs round the face aperture of the hood and ties under the chin, and tapes and elastic draw the sleeves closely round the wrists Gum boots and long fabric gloves are also to be worn, and masks if desired Protective clothing is absolutely necessary for members of the team, since any of them may come into contact with typhus infected lice During removal to hospital the patient should be enveloped in a large sheet, and should travel in a vehicle which is easy to free from lice The staff engaged in admitting the patient to hospital are particularly exposed to danger, and the greatest care of all should be taken during this time The patient must be admitted to a special bathroom, stripped, deloused and clad in hospital clothing before being taken to a ward set aside for the purpose Delousing must include not only complete disinfestation of the patient's clothing but careful delousing of his person, close cutting of the hair, shaving where necessary and careful bathing He must be thoroughly soaped all over and cleansed in such a way that all lice are destroyed In the hospital a room must be provided where the staff can change into protective clothing After use the clothing must be left there for disinfection, the staff must pass next to a bath room and finally to the room where their ordinary clothing is kept

Officers with experience of typhus in the medical department of the Ministry of Health or in the L C C will help to advise on diagnosis, and arrangements have been made for a mobile team from the American Red Cross—Harvard Field Hospital Unit—to give help in diagnosis and control in any part of England or Wales Medical officers of health are advised to arrange for beds to be available in the larger isolation hospitals The origin of infection must be carefully traced and all those who have been exposed to risk must be deloused and kept under observation for three weeks Heavily infested people may have to be deloused a second time after an interval of ten days to ensure destruction of lice hatched from surviving eggs

INCIDENTS AND GAS

HANDBOOKS to prepare the peaceable against the demands of war are the fashion just now, and a good thing too No one can say "Why wasn't I told?" Three such warning messengers have lately been launched by Jordan and Sons Mr W F F Shearcroft's 24-page booklet (War Gases Learn and Live 6*d*) deserves a wide sale It includes all the man in the street need know about gas, and by means of excellent little illustrations and apt descriptions paints as vivid a picture of a gas attack as you can hope to get for sixpence Mr T E Browne's 48 pages (Conduct of A R P Incidents, 1*s*) contain little that will be new to doctors, but the book may have uses for incident officers So will the folded card (Duties of an Incident Officer, 1*d*), by Mr R D Wormald and Mr J M Young, but this again does not aim at instructing the casualty services

---

LIQUEMIN HEPARIN—Roche Products Ltd have changed this solution which is now about 2½ times as strong as the old solution The potency of the new solution will be stated in terms of Toronto units, viz, 1,000 T U per 1 c cm, or 5,000 per 5 c cm phial

Births, Marriages and Deaths

BIRTHS

COPE—On Nov 18, at Ongar, the wife of Major R W Cope, R A M C—a daughter

KERR—On Nov 16, at Inverness, the wife of Dr England Kerr, —a daughter

SHAW—On Nov 21, at Berkhamsted, the wife of Dr C Carter Shaw —a son

SMALLEY—On Nov 17, at York, the wife of Captain C S Smalley, R A M C—a son

TEMPLETON—On Nov 22, at Leicester, the wife of Major William Templeton, R A M C—a son

WILLIAMS—On Nov 15 at Oxford, to Joyce Beverley Williams, M B, wife of Squadron Leader Denis Williams, M R C P, R A F V R—a daughter

MARRIAGES

SYMON—MOORE—On Nov 20 at Quainton, David Symon to Jocelyn Moore, F R C S R A M C

DEATHS

BLACK—On Nov 23, at South Croydon, Thomas Anthony Black, M B N U I

CHIDELL—On Nov 18 at Hythe, Claude Churchill Chidell, M B Lond, first superintendent of Pinewood Sanatorium

GOFF—On Nov 21, at Ventnor, Isle of Wight, Bruce Edward Goff, M B Glasg late of Ovington Gardens London

LINNELL—On Nov 18, at Northampton, Alfred Linnell, M R C S, aged 80 years

PILKINGTON—On Nov 21, at Parkstone Dorset, Frederick William Pilkington M R C S D P M, aged 83

SMYTH—On Nov 23, at Bognor Regis Ernest Jackson Smyth, M D Lond

SANDEMAN—On Nov 22, at Hertford, Muir Sandeman, M B Edin, aged 75

WEST—On Nov 20 at Queen Mary's Hospital, Carshalton, Henry Owen West, M D Lond, F R C P

Appointments

CLINE H R, M B N U I D L O surgeon to the ear nose and throat department of the Mildmay Mission Hospital, London

HODGES W V A, L D S dental officer for Dorset

MAWSON EDWIN L M D Lpool temp asst T O for Bristol and R M O at Frenchay Park Sanatorium

PHILLIPS H I, L D S dental officer for Dorset

SHAW, DAVID M D Lond, M R C P temp L C C specialist at Sutton Emergency Hospital

Dawson did not produce real frostbite by cold alone without the assistance of damp or constriction I am at present investigating this point afresh The two investigations agree in this, that the tissue damage is wrought by vasodilatation and exudation and not by vasoconstriction, which is a transitory phenomenon only. While the vessels are constricted little transudation takes place, especially if the venous return is free and capillary pressure therefore low When, by destruction of the arteriolar walls by cold or by the passing off of the constriction as the tissues thaw the vessels dilate, exudation and damage follow. This conception is confirmed by the observations of Lewis and Love (1926) and by my own recent unpublished experiments

Warmth —After the primary effects of cold the most dangerous causal element is warmth during the time of thaw That great heat is dangerous has been recognised at any rate since the time of Larrey (1812) and is part of the folk-knowledge of the Eskimos It is curious that the natives of the Himalayas have not learned this I have more than once forcibly prevented Tibetans and Nepalis from roasting or boiling their chilled feet That even slight degrees of warmth are dangerous is not realised by many even today Smith, Ritchie and Dawson (1915) showed that when the tissues of the feet have been damaged by cold water at only 37° C causes a rapid œdema or a rapid increase in œdema already present Lewis and Love (1926) showed that this œdema is excessive and injurious and went so far as to suggest the temporary obstruction of the arterial supply to frostbitten limbs My own experiments show that gentle warmth greatly increases the amount of tissue lost after freezing

Damp —It has already been pointed out that, in the presence of cold mud at temperatures even above freezing-point, a form of frostbite develops which is different only in the slowness of its onset from gradual frostbite due to greater cold alone This is in part due to the fact that water is a much better conductor of heat than air Further it has been shown by Lewis and Love (1926) that variations exist in the freezing-point of human skin between the extremes of – 2 2° C and – 25° C These variations occur not only between individuals but in the same individual at different times They are due to the phenomenon of super-cooling—the capacity of a substance to go below its ordinary freezing-point without solidifying Supercooling does not harm the tissues; freezing does The capacity to supercool may be abolished by soaking the skin in water, and skin which does not supercool may be induced to do so by leaving it unwashed for a week or by rubbing in oil an observation which explains the efficacy of whale oil as a prophylactic

Circulatory stagnation —Obviously the maintenance of a brisk circulation is an important preventive of cold feet Larrey, in the Napoleonic wars, made his men take brisk exercise in the cold The Crimean war observations have already been quoted Nevertheless, exhausted men will often forget so simple a fact and in the trench warfare of 1914–18 constant vigilance was required, but not always shown, by platoon commanders to prevent men from standing for long periods slumped motionless against the parapets of the trenches The venous return from the legs depending largely on muscular activity it is necessary that this activity should be maintained if increased venous pressure, increased capillary pressure and consequent œdema are to be prevented Active obstruction of the venous return is still more dangerous and may arise from clothing such as tight boots, tight garters and even tight gloves or socks, though puttees have at last been discarded It may arise also from compression of the popliteal space In the last war men were apt to sit for long periods, often to sleep, with the sharp edge of the fire-step compressing their thighs, just as in this war shelter-dwellers have compressed their thighs with the edge of deck-chairs The same factors are undoubtedly at work—venous stagnation, caused by uneasy sleep on hard chairs cold, and often damp, with resulting rise in capillary pressure, transudation, and, in the rare severe cases tissue damage Smith Ritchie and Dawson (1915) showed that slight constriction of the legs of their rabbits by rubber bands greatly increased the destructive effects of cold

Wind —The cooling effect of wind, increasing the evaporation of sweat and blowing away the layer of warm air about the body is of great practical importance Frostbite does not occur in New York in the absence of wind until the temperature falls to – 13 3° C (Brahdy 1935)

Anoxia —Persons suffering from anoxia from any cause are more liable than others to suffer tissue damage from the effects of cold The anoxia may be anæmic as in the anæmic diseases, poisoning with nitrites or carbon monoxide, or after severe hæmorrhage, stagnant, as in heart failure and wound shock; histotoxic, as in cyanide poisoning and under general anæsthesia; or due to reduction of atmospheric oxygen pressure The first three are chiefly important because men suffering from hæmorrhage and shock are likely to be subjected in winter air-raids to severe cold If such a man must be given an anæsthetic—which not only renders him almost poikilothermic but depresses his tissue oxidation by interfering with the reduction of cytochrome —great care should be taken to protect him from cold The presence of frostbite may well tip the balance in favour of transfusion. Blood should be used rather than plasma, in order that the oxygen-carrying capacity of the blood should be increased The fluid balance must be carefully watched, and any temptation to overdo it, and thus risk increased œdema, strongly resisted

Anoxia due to reduced pressure of atmospheric oxygen is important because patients suffering from emphysema, pneumonia, blast injury to the lungs or the shallow breathing of neurasthenia are very vulnerable; and because of the association of low temperatures with great altitudes At such altitudes, anoxia produces its effects not only by depriving the tissues of oxygen but by its effects on the circulation Acute anoxia first causes an apparent increase in the force of the heart, but the effect is only temporary. The heart muscle is depressed the blood-pressure falls and the minute-volume is reduced (Doi 1921, Schneider 1921, Barcroft 1925 Barcroft Bock and Roughton 1921) When the supply of oxygen is deficient, the skin bears the brunt, the blood being shunted to more important organs Thus the skin is more liable to frostbite not only because the blood carries less oxygen but because it gets less blood The warming effect of oxygen at great altitudes is most obvious and its effect in incipient frostbite extremely valuable (Greene 1934 and 1940a)

Nutritional deficiency —" The Medical History of the Crimean War " (1858) drew attention to defective nutrition and concurrent disease such as fever or scurvy as predisposing factors in the production of frostbite Captain R F Scott's ill-fated polar expedition was crippled by frostbite, though experienced arctic and antarctic explorers are rarely so severely smitten The diet of the party was certainly scorbutic a fact of which Scott had been warned The relationship is easy to understand The main feature of scurvy is hæmorrhage, which may show itself in any organ of the body but which is especially noticeable in the skin The various features of the complete syndrome are becoming gradually associated with deficiency of a variety of vitamins Thus the night-blindness often present is now recognised as a symptom of hypovitaminosis A while evidence is emerging that the increased capillary permeability may be a combined effect of lack of vitamins C and P, lack of the former producing ecchymosis and of the latter petechiæ (Scarborough 1940) However this may be it is clear that a deficiency of one or other of these vitamins is capable of increasing that exudation from the blood-vessels which is the most important damaging factor in frostbite and trench-foot

In starvation, too, œdema already present may increase the damage due to frostbite It is thought that the low protein intake results in a low concentration of plasma proteins and a consequent transfer of fluid osmotically to the adjacent tissues, but the relative importance of this factor and of the vitamin deficiencies associated with starvation has not been determined

Trauma —Age-old tradition demands that a frostbitten limb should be rubbed with snow Many of those who have discarded the snow which is probably harmless have continued the rubbing As I have already explained (Greene 1940b), the skin of a frostbitten limb is in a most delicate state, and the gentlest rubbing may night in a sitting position without compensating rest in a horizontal position during the day The condition was further described in a leading article in THE LANCET of Dec 7 1940 (p 722) Beginning in the feet, the swelling extended up the leg , it was painless at first, but afterwards became painful and in some cases the skin became shiny and red Knight observed that the condition did not arise in wardens who though exposed to the same degrees of cold and damp were frequently on their feet and that most of his patients had used deck-chairs, the wooden bars of which had exerted prolonged pressure on the popliteal fossa That pressure was an ætiological factor was shown by the observation that those who sat with one leg crossed over the other developed swelling in the lower leg only Knight described the appearances of this ailment as reminiscent of trench-foot I saw one of these patients in consultation with him

CASE 1 —A middle aged baker Both feet were very œdematous, the swelling extending a short way above each ankle and gradually fading into the thickness of the calf The skin of the feet and the lower half of the legs was covered with a very fine petechial rash On applying Gothlin's test to the arm, it was found that the patient's general capillary permeability was greatly in excess of normal, and, in the absence of *any other discoverable abnormality, the question* of dietary deficiency naturally arose The patient had "studied all this diet nonsense" and come to the conclusion that it was "all a doctor's racket" He particularly resented the efforts of doctors to suppress the white loaf, which he considered the only bread fit to eat He disliked green vegetables, but ate them occasionally to please his wife He never ate fruit of any kind He worked 18 hours a day and developed the swelling *of the feet after a night spent sitting* on a hard chair in his bakery

Clinical research outside hospital is notoriously difficult Patients who are not under one's eye disobey instructions or disappear at important moments, often never to return Further investigations on the baker were not possible and all that is known is that after a change in his diet and his chair he made a complete recovery Four other patients were afterwards seen

CASE 2 —A woman, who also had an increased capillary permeability Estimation of her urinary excretion of ascorbic acid by the method of Harris and Abbasy (1937) showed deficiency of vitamin C Treatment with ascorbic acid, 50 mg t d s,, was followed by a rapid recovery and the return of her capillary permeability to normal

CASE 3 —A woman who had spent every alert sitting in a shelter, was found on inquiry to be eating a diet apparently deficient in vegetables By Harris and Abbasy's test she did not appear to be deficient in vitamin C She was given vitamin P in the form of hesperidin, 1 g daily Her legs and capillary permeability returned to normal

CASE 4 —A woman who had been sitting up in her dining-room during alerts for 3 months and was taking a diet which seemed to be deficient in vitamin C Her capillary permeability and ascorbic acid excretion test were normal, however, and an opportunity to try vitamin P did not occur Her after-history is unknown

CASE 5 —A woman in whom only one leg—that over which she normally crossed the other—was affected was living on a diet deficient in vegetables Her capillary permeability was increased Advice on diet was followed by recovery and return to normal capillary resistance

These cases suggest that in shelter-foot the most potent causative factors are venous stagnation and increased capillary permeability Whether the latter is due to deficiency of vitamin C or vitamin P or to some other cause remains doubtful, but it is likely that as in the Crimean war dietetic deficiency played a part in the foot troubles of the battle of Britain The shortage of citrous fruits (the main source of vitamin P in modern diets) may conceivably be important We know of no action of vitamin P other than its effect of reducing capillary permeability A deficiency in normal times might well pass unnoticed only to be brought to light by the abnormal habits of war

IMMERSION-FOOT

I have never seen a case of immersion-foot, and for its adequate description we must await the reports of those whose war experience has brought them greater opportunities of observing it I gather that clinically it is almost identical with trench-foot and that the are the same In recent experiments I have succeeded in producing in the tails of mice immersed for long periods in sea-water a condition histologically indistinguishable from trench-foot and it therefore seems that prevention and treatment of the two conditions should be by the same means

CAUSES

Cold —Many of the effects of cold are too well known to need more than passing reference Chilling of the body generally is counteracted mainly by endocrine and reflex nervous mechanisms, both perhaps controlled by the hypothalamus Cold stimulates the adrenal glands with a resulting constriction of skin vessels and diminution of heat loss With a heat debt of less than 900 small calories per kg the adrenaline reaction is sufficient At the same time the thyroid is stimulated,-cellular metabolism is increased and more heat is produced With greater heat debts this mechanism is aided by reflex shivering (see Cramer 1928) Were this the whole story general chilling would be an even more potent cause of frostbite than it is, but the general contraction of the blood-vessels of the skin may be locally overcome by mechanisms which have been elucidated by Sir Thomas *Lewis and his associates Freezing of the skin results* in the release of H-substance from the damaged area which causes local vasodilatation (Lewis and Love 1926), a mechanism which can be observed in the colour changes of sudden frostbite An increased blood-flow through the extremities is also produced by the opening of arteriovenous anastomoses in the skin (Grant and Bland 1931) It is of great clinical importance that local vasodilatation may fail if the whole body is severely chilled (Lewis 1931)

The effects of cold with special reference to frostbite were studied by Rischpler in 1900 He froze animal tissues by the application of ice and salt and investigated the results microscopically at various intervals Degeneration occurred early in the cells of the vessel walls with swelling of the connective tissues, and vacuolation of the muscle-fibres in the media There was œdema, but no sign of thrombosis His findings were confirmed with less severe freezing by Smith, Ritchie and Dawson (1915), who showed that the chief, and only important effect of cold short of total destruction of the tissues is on the vessels These show dilatation of the lumen swelling of the intima and vacuolation in the media , there is no thrombosis In other tissues, the effects depend on œdema—in other words, on transudation from the blood-vessels The initial contraction of the blood-vessels due to cold is rapidly supplanted by dilatation of the damaged vessels An excessive amount of fluid is poured out into the tissues and there may even be rupture and hæmorrhage The fibrous bundles of the connective tissues are separated by fluid and become swollen and disintegrated Other surrounding tissues share this fate in varying degree According to these workers, the effects of mild wet cold differ only in degree from those of severe dry cold short of actual freezing Their conclusions are of the more importance because they succeeded in producing in the feet of their rabbits conditions closely similar to some forms of frostbite in man

In 1917, Lake, in a beautiful series of experiments with a large variety of tissue-cultures of man and other animals drew a hard and fast distinction between degrees of cold which solidified tissues (sudden frostbite in clinical terminology) and lesser degrees His critical temperature was − 6° C both in cultures and in tissues in their normal relationship with vessels and nerves It is interesting to compare the observation of Brahdy (1935) that men working in the streets of New York are not frostbitten even in a high wind till the temperature falls to − 14° C Below − 6° growth of Lake's cultures ceased, blood was hæmolysed, and destruction of intact skin occurred Above it tissue-cultures retained their functional and vegetative vitality, blood-cells survived, and only a transient hyperæmia occurred in the intact human skin At first sight these findings appear to contradict those of Smith, Ritchie and Dawson who found quantitative differences only between the effects of prolonged mild cold and short exposures to extreme cold Further consideration shows that the two results are not necessarily incompatible for Smith, Ritchie and

Dawson did not produce real frostbite by cold alone without the assistance of damp or constriction. I am at present investigating this point afresh. The two investigations agree in this, that the tissue damage is wrought by vasodilatation and exudation and not by vasoconstriction, which is a transitory phenomenon only. While the vessels are constricted, little transudation takes place, especially if the venous return is free and capillary pressure therefore low. When, by destruction of the arteriolar walls by cold, or by the passing off of the constriction as the tissues thaw, the vessels dilate, exudation and damage follow. This conception is confirmed by the observations of Lewis and Love (1926) and by my own recent unpublished experiments.

Warmth.—After the primary effects of cold the most dangerous causal element is warmth during the time of thaw. That great heat is dangerous has been recognised at any rate since the time of Larrey (1812) and is part of the folk-knowledge of the Eskimos. It is curious that the natives of the Himalayas have not learned this. I have more than once forcibly prevented Tibetans and Nepalis from roasting or boiling their chilled feet. That even slight degrees of warmth are dangerous is not realised by many even today. Smith, Ritchie and Dawson (1915) showed that when the tissues of the feet have been damaged by cold, water at only 37° C causes a rapid œdema or a rapid increase in œdema already present. Lewis and Love (1926) showed that this œdema is excessive and injurious and went so far as to suggest the temporary obstruction of the arterial supply to frostbitten limbs. My own experiments show that gentle warmth greatly increases the amount of tissue lost after freezing.

Damp.—It has already been pointed out that, in the presence of cold mud at temperatures even above freezing-point, a form of frostbite develops which is different only in the slowness of its onset from gradual frostbite due to greater cold alone. This is in part due to the fact that water is a much better conductor of heat than air. Further, it has been shown by Lewis and Love (1926) that variations exist in the freezing-point of human skin between the extremes of − 2.2° C and − 25° C. These variations occur not only between individuals but in the same individual at different times. They are due to the phenomenon of super-cooling—the capacity of a substance to go below its ordinary freezing-point without solidifying. Supercooling does not harm the tissues; freezing does. The capacity to supercool may be abolished by soaking the skin in water, and skin which does not supercool may be induced to do so by leaving it unwashed for a week or by rubbing in oil, an observation which explains the efficacy of whale oil as a prophylactic.

Circulatory stagnation.—Obviously the maintenance of a brisk circulation is an important preventive of cold feet. Larrey, in the Napoleonic wars, made his men take brisk exercise in the cold. The Crimean war observations have already been quoted. Nevertheless, exhausted men will often forget so simple a fact and in the trench warfare of 1914–18 constant vigilance was required, but not always shown, by platoon commanders to prevent men from standing for long periods slumped motionless against the parapets of the trenches. The venous return from the legs depending largely on muscular activity, it is necessary that this activity should be maintained if increased venous pressure, increased capillary pressure and consequent œdema are to be prevented. Active obstruction of the venous return is still more dangerous and may arise from clothing such as tight boots, tight garters and even tight gloves or socks, though puttees have at last been discarded. It may arise also from compression of the popliteal space. In the last war men were apt to sit for long periods, often to sleep, with the sharp edge of the fire-step compressing their thighs, just as in this war shelter-dwellers have compressed their thighs with the edge of deck-chairs. The same factors are undoubtedly at work—venous stagnation caused by uneasy sleep on hard chairs, cold, and often damp, with resulting rise in capillary pressure, transudation, and, in the rare severe cases, tissue damage. Smith, Ritchie and Dawson (1915) showed that slight constriction of the legs of their rabbits by rubber bands greatly increased the destructive effects of cold.

Wind.—The cooling effect of wind, increasing the evaporation of sweat and blowing away the layer of warm air about the body, is of great practical importance. Frostbite does not occur in New York in the absence of wind until the temperature falls to − 13.3° C (Brahdy 1935).

Anoxia.—Persons suffering from anoxia from any cause are more liable than others to suffer tissue damage from the effects of cold. The anoxia may be anæmic, as in the anæmic diseases, poisoning with nitrites or carbon monoxide, or after severe hæmorrhage; stagnant, as in heart failure and wound shock; histotoxic, as in cyanide poisoning and under general anæsthesia; or due to reduction of atmospheric oxygen pressure. The first three are chiefly important because men suffering from hæmorrhage and shock are likely to be subjected in winter air-raids to severe cold. If such a man must be given an anæsthetic—which not only renders him almost poikilothermic but depresses his tissue oxidation by interfering with the reduction of cytochrome—great care should be taken to protect him from cold. The presence of frostbite may well tip the balance in favour of transfusion. Blood should be used rather than plasma, in order that the oxygen-carrying capacity of the blood should be increased. The fluid balance must be carefully watched, and any temptation to overdo it, and thus risk increased œdema, strongly resisted.

Anoxia due to reduced pressure of atmospheric oxygen is important because patients suffering from emphysema, pneumonia, blast injury to the lungs or the shallow breathing of neurasthenia are very vulnerable; and because of the association of low temperatures with great altitudes. At such altitudes, anoxia produces its effects not only by depriving the tissues of oxygen but by its effects on the circulation. Acute anoxia first causes an apparent increase in the force of the heart, but the effect is only temporary. The heart muscle is depressed, the blood-pressure falls and the minute-volume is reduced (Doi 1921, Schneider 1921, Barcroft 1925, Barcroft, Bock and Roughton 1921). When the supply of oxygen is deficient, the skin bears the brunt, the blood being shunted to more important organs. Thus the skin is more liable to frostbite not only because the blood carries less oxygen but because it gets less blood. The warming effect of oxygen at great altitudes is most obvious, and its effect in incipient frostbite extremely valuable (Greene 1934 and 1940a).

Nutritional deficiency.—"The Medical History of the Crimean War" (1858) drew attention to defective nutrition and concurrent disease such as fever or scurvy as predisposing factors in the production of frostbite. Captain R. F. Scott's ill-fated polar expedition was crippled by frostbite, though experienced arctic and antarctic explorers are rarely so severely smitten. The diet of the party was certainly scorbutic, a fact of which Scott had been warned. The relationship is easy to understand. The main feature of scurvy is hæmorrhage, which may show itself in any organ of the body but which is especially noticeable in the skin. The various features of the complete syndrome are becoming gradually associated with deficiency of a variety of vitamins. Thus the night-blindness often present is now recognised as a symptom of hypovitaminosis A, while evidence is emerging that the increased capillary permeability may be a combined effect of lack of vitamins C and P, lack of the former producing ecchymosis and of the latter petechiæ (Scarborough 1940). However this may be it is clear that a deficiency of one or other of these vitamins is capable of increasing that exudation from the blood-vessels which is the most important damaging factor in frostbite and trench-foot.

In starvation, too, œdema already present may increase the damage due to frostbite. It is thought that the low protein intake results in a low concentration of plasma proteins and a consequent transfer of fluid osmotically to the adjacent tissues, but the relative importance of this factor and of the vitamin deficiencies associated with starvation has not been determined.

Trauma.—Age-old tradition demands that a frostbitten limb should be rubbed with snow. Many of those who have discarded the snow which is probably harmless have continued the rubbing. As I have already explained (Greene 1940b), the skin of a frostbitten limb is in a most delicate state, and the gentlest rubbing may well destroy its chance of survival. The tail of a mouse frozen and then gently rubbed suffers damage as severe as if it is warmed before the fire, a practice recognised as harmful. It is clear, too, that rubbing must increase the risk of infection, a complication greatly to be feared. Andrews (1941), after a trial of my methods, agreed that gentle methods give the best results.

These factors—cold, warmth after cold, damp, venous stagnation, wind, anoxia, nutritional deficiency and trauma—may all play a part in the production of the various forms of the ailment. Thus in true *frostbite*, the immediate cause is cold, aggravated often by wind and anoxia and occasionally by the other factors. In trench-foot and immersion-foot, damp is probably the most important factor, associated usually with cold and venous stagnation and often by the others. In shelter-foot, venous stagnation is apparently the primary cause, perhaps with dietetic deficiency as a partner and certainly often with cold and damp as assistants. Though the causes vary in relative importance from case to case, they act through a common channel—transudation from damaged blood-vessels. The prevention and treatment of the four variants can therefore be discussed together.

PREVENTION

Frostbite is usually preventable. Nowadays among experienced explorers and mountaineers it seldom occurs severely, and then only in circumstances which are beyond their control. Despite the severe conditions in various theatres of the last war, some units were almost untouched. Experience gained then should make trench-foot a rarity now, and consideration of the principles which I have outlined should greatly lessen and, indeed, have already greatly lessened, the incidence of both sudden and gradual frostbite. In the winters 1914–18, it was found that long rapid marches were dangerous, the men arriving in the trenches with feet sodden with sweat, probably swollen by their exertions and often rubbed by ill-fitting boots. Whenever possible, then, the last march should be a short one. The importance of dry socks was recognised in a number of Army orders. In an order of the First Army in January, 1915, it was laid down that every man was to carry in his pack an extra pair of socks and was to change them at least once in 24 hours. Careful attention should be paid to the construction of trenches. In many districts proper drainage will keep trenches dry even in wet weather. When this is impossible, duckboards must be provided. The men should wear gum-boots. These should not be used for long marches because they are impermeable and retain sweat. In many places in the last war, a boot store was kept just behind the front line. Men going to the trenches took off their own boots, which were marked and stored, and were supplied with dry gum-boots. On leaving the trenches they exchanged these for their own boots. The gum-boots were dried by passing into the toes a rubber tube attached to a six-foot length of iron pipe. To the other end of the pipe was fixed a hand bellows. The pipe was laid across a brazier and a stream of hot air pumped into the toes of the boots. Whenever possible, the period of duty in the trenches should not exceed 24 or at the most 36 hours, and it should be remembered that the transfer of a man from a muddy trench to a billet does not end the danger if he continues to wear wet socks and boots. Some medical officers of the last war were able to arrange that at least once a day a pair of clean dry socks should go up with the rations to every man in the trenches. These rations should be hot; carriers working on the hay-box principle make this possible, and the supply of "Tommy's cookers" should be large.

Officers should watch for habits in their men likely to lead to trench-foot. It is dangerous to sleep sitting with the edge of the seat or fire-step compressing the back of the thigh. Whenever possible men should sleep lying down with their feet up, wearing their overcoats and as many blankets as possible. They should not stand still, but should move about, raise themselves on their toes, and in general keep the muscles of the legs in constant activity. They should be warned of the danger of touching bare metal on very cold days. Boots should be unlaced at every opportunity.

Clothes should be loose and in many layers. Two thin layers are warmer than one thick one, for the chief warmth lies in the imprisoned air. The outside layer should be of light windproof material like Grenfell cloth. Two pairs of socks should be worn, but only if the boots are large enough to take them easily. Tight socks are as dangerous as tight boots. Darned socks are dangerous because they make blisters. Boots must be kept supple with grease or heavy oil, especially at the flexure of the uppers. The gloves should be of wool, but an outer waterproof glove should be worn also, for wool is neither windproof nor waterproof. Gloves are of special importance in the R.A.F., air-gunners being particularly exposed to frostbite. Their work cannot be done in large and cumbersome gloves, but these should be carried on a string round the neck. The hands can then be protected when not in use but instantly removed when needed. It is in this way that mountaineers protect their hands during the periods of waiting on difficult climbs. Thin silk gloves worn continuously, and thus reinforced when possible, are a valuable protection if they can be kept dry. Hot packs † are dangerous. They are good protectors, but may be most harmful if frostbite has already developed. Perhaps it is a good thing that at very high altitudes they cease to function. *Foot drill is necessary in cold trench warfare.* It should be carried out before going into the trenches, if possible once a day or more while in the trenches, and again when leaving. During the winter of 1917–18 foot-drill centres were established, one for each brigade, near the front line.

At such centres the men sit in pairs, facing each other. Each man removes his companion's boots and socks, and if water is available washes his feet and carefully dries them. Any sores or abrasions are immediately reported to the medical officer and the man is relieved from duty till the skin is healed. It may seem that a very large number of men would be off duty for this cause for long periods, but in fact it is found that the number of casualties from foot troubles is greatly reduced. Each man then rubs into his companion's feet by a process of gentle massage a quantity of whale oil. It is no use just putting the oil on the feet; it must be rubbed in until it has disappeared. The quantity needed is 10 gallons per day per battalion. Dry clean socks are then put on.

Despite the difficulties of trench warfare and the opposition at first of many commanding officers, foot drill was carried out regularly in many units. It was popular with the men, and the drop in casualties from trench-foot finally convinced the sceptics. I recommend this Army experience to the notice of the senior service and to all who go down to the sea in ships, collapsible boats or Carley floats.

TREATMENT

If, despite all care or because of its lack, cases occur, treatment depends on the stage at which it is undertaken, not on the clinical type of frostbite. The premonitory symptom may be a white patch on the face, for which men in very cold conditions should be trained to watch. This can usually be cured by the immediate application for a few seconds of a warm ungloved hand. If feet or hands become numb no time must be lost. Boots and socks or gloves must be instantly removed and the limb warmed by placing it inside another man's clothes. *Gentle massage may be used,* but it should not be continued for more than a few minutes. Rubbing the affected parts, with or without snow, is extremely dangerous. Either the tissues are dead, in which case they are beyond care, or they are still alive. If they are still alive, the application of the most gentle warmth, never greater than that of the human body, will quickly restore the circulation; *friction can only harm delicate* and perhaps brittle tissues, and by increasing exudation increase damage. If these measures fail to restore warmth, the affected part should be thoroughly but gently cleaned, painted with an active antiseptic such as proflavine, wrapped in sterile dressings and in many layers of wool, and given complete rest. A man with only slightly frostbitten feet is a stretcher case. A frostbitten hand must be carried in a sling. Antitetanus serum should be given, for tetanus after frostbite is common and very fulminant (Andrewes 1923). The patient should be given hot food and drinks and extra clothes and removed as quickly as possible to a place of comparative warmth and security. If the frostbite has occurred at a height above sea-level, whether in an aeroplane or on a mountain, pure oxygen should be given either with the B L B mask or with the simpler face-piece of my design (Greene 1934b) until sea-level is reached. Thereafter, a policy of masterly inactivity should be pursued unless sepsis develop, in which event it should be treated like sepsis from any other cause. Excessive warmth should be avoided throughout, hot cradles being specifically forbidden. Between the part irretrievably doomed to gangrene (if such there be) and the part never endangered there is probably an area striving for life in a state of anoxia. Heat to this part will increase its metabolism and its oxygen requirements, and will encourage the growth of bacteria. Frostbitten parts must be kept cool.

---

† Hot packs are metal boxes containing a chemical source of heat. At great altitudes there is insufficient oxygen for the heat producing chemical reaction to take place.

A number of active treatments have been suggested, but are still sub judice. Short-wave treatment has been advocated by Burkmann (1934) but it is difficult to see what good could come of it. Passive vascular exercise is popular in the United States but has been little used here and nowhere under properly controlled conditions. It appears at first sight to be dangerous, for should the arterial supply to the limb be increased the capillary pressure would be further raised and transudation increased. On the other hand, if pressure-changes were used sufficient only to effect the venous side of the circulation the capillary pressure would be lowered and good might come. I hope to be able to provide some experimental evidence on this point later.

Recent publications (Soupault and Orsone 1940, Simon and Filhouland 1940, Forster and Wiederkehr 1940, Stricker and Buck 1940) have described the use of lumbar injections of procaine and allied compounds, of femoral sympathectomy, and of injections of the stellate ganglion. It is difficult to see how treatment producing vasodilatation could possibly do anything but harm in the acute stage. The suggestions of Lewis and Love (1926) that the arteries should be obstructed, and of Lake (1917) that they should be constricted are more rational. After the acute stage, healing takes place in any event, and though vasodilatation might conceivably hasten the process the treatment seems hardly worth while. Happily none of the cases reported were seen until a time when they were probably well on the way to spontaneous recovery, but it is to be hoped that without careful previous animal experiments no surgeons will be tempted to follow in the footsteps of these French colleagues.

Amputation is, in the absence of uncontrollably spreading sepsis, seldom necessary and never urgent. In the last war hundreds of limbs were unnecessarily lopped off because they were black and of alarming appearance. I have described a case (Greene 1940a) in which the feet were black and hard to 3 in. above the ankle, where a clear line of demarcation might have tempted a surgeon. Below this level the woody tissues obscured the pulsation of the arteries. I am not a surgeon and I left well alone. The gangrenous skin peeled off little by little like a sock, leaving healthy skin beneath. Two months later the little toes and the terminal phalanges of the others were amputated in the comfort of a hospital—as a matter of convenience not of necessity even then. A porter on the 1933 Everest expedition was frostbitten in establishing camp 6 at 27,390 ft. Two of his fingers were black and hard to the proximal interphalangeal joints. After a short time he refused to wear dressings. When he returned to Darjeeling he refused to have his fingers amputated; he liked them like that. Presumably they fell off in the end. We should never, therefore, amputate hurriedly any part of the body afflicted with uncomplicated frostbite. Amputation may be advisable later for æsthetic or orthopædic reasons. That question can be left to the unhurried judgment of a surgeon working amid the conveniences of a hospital at home.

SUMMARY

Frostbite and the kindred conditions of trench-foot, shelter-foot and immersion-foot are produced by combinations in differing proportions of many causes, the most important being cold and damp. Of secondary, but still great, importance are excessive warmth during recovery, circulatory stagnation, wind, anoxia, dietetic deficiencies, and trauma, especially during ill-directed treatment. By bearing in mind the causes, and especially by proper care of the feet, most cases are preventable. Those cases which occur despite all care, are usually less alarming than they appear to be.

The treatment consists of the avoidance of trauma and infection. Amputation is seldom necessary, and in the absence of spreading infection, is never urgent.

THE RESPONSE TO VITAMIN K

A LIVER-FUNCTION TEST

ROBERT KARK,
M R C P
ROCKEFELLER TRAVELLING FELLOW, MEDICAL RESEARCH COUNCIL, 1939-40

ALEXANDER W SOUTER,
M B ABERD
GEORGE THOMPSON FELLOW, ABERDEEN UNIVERSITY, 1938-40

RESEARCH FELLOWS, HARVARD MEDICAL SCHOOL AND THORNDIKE MEMORIAL LABORATORY, BOSTON, MASS

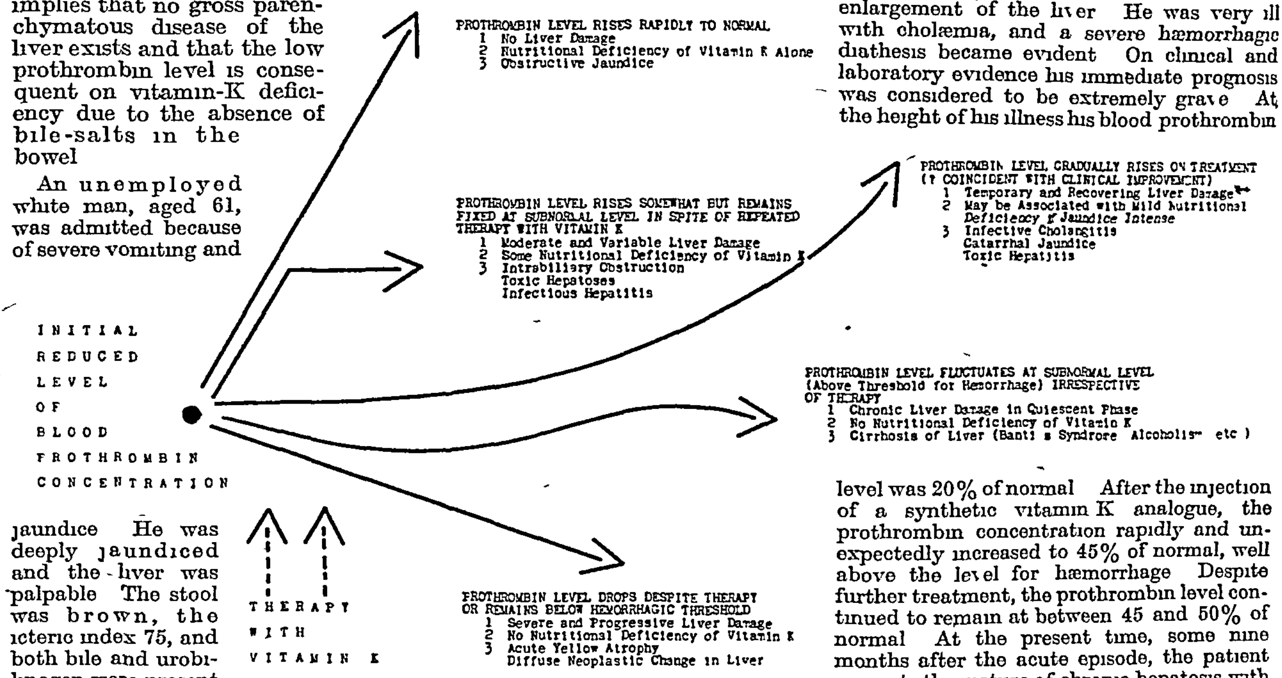
THE experimental evidence in support of the hypothesis that the liver plays an essential rôle in the production of prothrombin is to be found in the work of Andrus and his colleagues (1939) and of Warren and Rhoads (1939), who by total and partial hepatectomy in animals produced a profound reduction in the blood prothrombin concentration which was not affected by treatment with vitamin K and bile-salts. The observations reported here have been made during the past two years, while we were studying the effect of various preparations of vitamin K on the prothrombin level. During this study it became obvious, as has been noted by others (e g. Butt, Snell and Osterberg 1939, Scanlon et al 1939), that some patients with liver disease and hypoprothrombinæmia do not show a satisfactory response to oral or parenteral therapy with vitamin K or its synthetic analogues. Smith, Warner and Brinkhous (1937), from the results of an experimental investigation of chemically induced liver damage in dogs, have suggested that the plasma-prothrombin level appears to be a fairly sensitive index of liver function provided there is not an associated vitamin-K deficiency.

Of approximately 200 of our patients suspected of having hypoprothrombinæmia, 57 were diagnosed clinically as having disturbances of the liver. Among these patients were cases of portal and biliary cirrhosis, catarrhal jaundice, toxic or infectious hepatitis, and patients with intense jaundice which created a difficult problem of differential diagnosis. In attempting to assess the type and extent of liver disorder present in these cases, instead of using the blood-prothrombin level alone, we tried to come to a conclusion from a study of two sets of data. These were the initial level of the blood prothrombin before the administration of vitamin K, and the character and degree of response following its administration

Analysis of the data accumulated showed that these 57 cases with clinically evident liver disease could be placed in five subdivisions A schematic representation has been devised (see figure) in which the response of the lowered blood-prothrombin levels to vitamin-K therapy in the patients in each of the five groups is represented by a curve considered typical for each group

GROUP I

The lowered prothrombin concentration in the blood rapidly (24–48 hours) returns to normal level (90–100% of normal) after therapy with vitamin K—When intense jaundice and well-marked hypoprothrombinæmia are present, and when the diagnosis is in doubt, the rapid and complete response of a lowered blood-prothrombin level to therapy with vitamin K indicates the probability of obstructive jaundice The good response to therapy implies that no gross parenchymatous disease of the liver exists and that the low prothrombin level is consequent on vitamin-K deficiency due to the absence of bile-salts in the bowel



PROTHROMBIN LEVEL RISES RAPIDLY TO NORMAL
1 No Liver Damage
2 Nutritional Deficiency of Vitamin K Alone
3 Obstructive Jaundice
PROTHROMBIN LEVEL RISES SOMEWHAT BUT REMAINS FIXED AT SUBNORMAL LEVEL IN SPITE OF REPEATED THERAPY WITH VITAMIN K
1 Moderate and Variable Liver Damage
2 Some Nutritional Deficiency of Vitamin K
3 Intrabiliary Obstruction
Toxic Hepatoses
Infectious Hepatitis
PROTHROMBIN LEVEL GRADUALLY RISES ON TREATMENT (? COINCIDENT WITH CLINICAL IMPROVEMENT)
1 Temporary and Recovering Liver Damage
2 May be Associated with Mild Nutritional Deficiency K Jaundice Intense
3 Infective Cholangitis
Catarrhal Jaundice
Toxic Hepatitis
INITIAL REDUCED LEVEL OF BLOOD PROTHROMBIN CONCENTRATION
PROTHROMBIN LEVEL FLUCTUATES AT SUBNORMAL LEVEL (Above Threshold for Hemorrhage) IRRESPECTIVE OF THERAPY
1 Chronic Liver Damage in Quiescent Phase
2 No Nutritional Deficiency of Vitamin K
3 Cirrhosis of Liver (Banti s Syndrome Alcoholism etc)
THERAPY WITH VITAMIN K
PROTHROMBIN LEVEL DROPS DESPITE THERAPY OR REMAINS BELOW HEMORRHAGIC THRESHOLD
1 Severe and Progressive Liver Damage
2 No Nutritional Deficiency of Vitamin K
3 Acute Yellow Atrophy
Diffuse Neoplastic Change in Liver

An unemployed white man, aged 61, was admitted because of severe vomiting and jaundice He was deeply jaundiced and the liver was palpable The stool was brown, the icteric index 75, and both bile and urobilinogen were present in the urine Because of a history of alcoholic excesses he was thought to have cirrhosis of the liver While under observation the stools were tan to yellow in colour the icteric index remained at between 50 and 100, and bile and urobilinogen persisted in the urine Because of "needle-puncture" hæmatomata a Quick prothrombin time was performed and showed a blood prothrombin level of 25% of normal Forty eight hours after injection of a synthetic vitamin-K analogue the blood-prothrombin level had reached 100% of normal On the basis of this good response to vitamin K it seemed that there was no gross disturbance of liver function and a diagnosis of vitamin K deficiency and obstructive jaundice was made During the next week the jaundice became more intense, the stools became pale and the icteric index rose to over 200 At laparotomy, an obstruction of the hepatic ducts was found, high up, which was considered to be of neoplastic origin The ducts themselves were much dilated, but because of their friability no major surgical intervention was attempted A portion of the liver taken for biopsy showed "slight acute cholangitis, with bile stasis, with no evidence of parenchymatous pathological changes" A cholangeogram performed after the operation showed dilated biliary and hepatic radicles with no dye entering the duodenum

GROUP 2

The lowered blood-prothrombin level rises somewhat but remains fixed at a subnormal level, despite repeated administration of vitamin K—This group of jaundiced patients have acute or subacute parenchymatous liver damage of a moderate and variable degree In them, swelling of hepatic cells exerts pressure on the intrahepatic ducts, and, following the development of intrabiliary obstructive jaundice, vitamin K is not absorbed from the bowel Therapy with synthetic vitamin-K analogues or with natural vitamin K and bile-salts remedies this nutritional deficiency, but, because of a moderate metabolic disturbance in the production of prothrombin by the liver, although the restoration of the blood-prothrombin level is rapid it is not complete The liver seems able to produce prothrombin, but in quantities insufficient to maintain a normal level in the blood If chronic hepatitis develops subsequently, then these patients will show the same type of response as those in group 4 (see figure), but if clinical improvement occurs there will be a return of the blood prothrombin from a subnormal to a normal level (cf group 3) In group 2 are found cases of catarrhal jaundice, toxic or infective hepatitis, cardiac failure with hepatosis, and also cases of so-called "fatty livers" which precede "alcoholic" cirrhosis

A boy, suffering with acute rheumatic fever and severe congestive heart failure, developed an acute parenchymatous hepatosis, characterised by deep jaundice and considerable enlargement of the liver He was very ill with cholæmia, and a severe hæmorrhagic diathesis became evident On clinical and laboratory evidence his immediate prognosis was considered to be extremely grave At the height of his illness his blood prothrombin level was 20% of normal After the injection of a synthetic vitamin K analogue, the prothrombin concentration rapidly and unexpectedly increased to 45% of normal, well above the level for hæmorrhage Despite further treatment, the prothrombin level continued to remain at between 45 and 50% of normal At the present time, some nine months after the acute episode, the patient presents the picture of chronic hepatosis with ascites and dilated abdominal veins The blood prothrombin has remained at the subnormal level

GROUP 3

The blood-prothrombin level gradually rises with treatment, coincident with clinical improvement—In this group of patients with liver disease, jaundice may or may not develop Fever is usually present and may be associated with an acute septic process, involving especially the biliary tree A moderately lowered blood prothrombin does not respond to therapy with vitamin K, or, if there is an immediate response, it is only slight This is because in the majority of these patients there is no true lack of vitamin K in the diet, but the prothrombin level is low because the liver is apparently unable to utilise the vitamin K absorbed from the gut If clinical improvement occurs, either through subsidence of an acute infectious process or because the initial liver disease clears up, then the prothrombin concentration in the blood will eventually reach a normal level In this group are found patients suffering with infective cholangitis, catarrhal jaundice, acute and toxic hepatosis, patients undergoing heat therapy, and patients suffering with obstructive jaundice complicated by an associated infective process

A housewife, aged 35, suffering with obstructive jaundice and hypoprothrombinæmia of 65% of normal, developed high fever, chills and liver tenderness suggestive of acute cholangitis There was no response to what was considered adequate therapy with a synthetic vitamin-K analogue, but after spontaneous remission of the acute symptoms further treatment with similar amounts of the synthetic vitamin-K analogue restored her blood-prothrombin level to normal within two days.

A labourer, aged 55, was admitted with jaundice. Five days previously he had developed anorexia, nausea and vomiting and a moderate degree of fever, and since then his stools had become pale and his urine dark. His skin was a deep lemon-yellow. The liver was palpable 3 cm below the costal margin, firm, smooth and not tender. The icteric index was 75. The stools were pale, and contained no blood. The urine contained bile and urobilinogen. A diagnosis of catarrhal jaundice was entertained. During his first week in the hospital there was some fever up to 102° F, while the icteric index fluctuated between 75 and 200. The blood-prothrombin level two weeks after the onset of illness was 65% of normal. Six days later the blood prothrombin had dropped to 45% of normal. He was given synthetic vitamin K intramuscularly, but the next day the blood prothrombin had dropped to 40% of normal. At this time the jaundice began to clear and there was obvious clinical improvement. However, there was no rapid response to repeated therapy with vitamin K, and the blood-prothrombin level rose gradually over a period of eight days, when it reached a normal level.

GROUP 4

The prothrombin level fluctuates at a subnormal level which is above the threshold for hæmorrhage, irrespective of therapy.—This group of patients have chronic and long-standing liver disease, usually unassociated with jaundice. The blood-prothrombin level usually fluctuates between 40 and 60% of normal and is not affected by therapy with natural or synthetic vitamin K, even when this is supplemented with a "high-vitamin" diet together with lightly broiled liver up to 300 g. per day and dried brewers' yeast concentrates by mouth (equivalent to 30 g. per day), and crude liver extracts given intramuscularly. In these patients there is no deficiency of vitamin K in the diet or evidence of its malabsorption from the gut, but the liver is not able to produce sufficient prothrombin to maintain a normal level in the blood (Kark and Souter 1940). Among these patients are found those suffering with cirrhosis of the liver and those presenting Banti's syndrome.

An unemployed man, aged 46, had been accustomed to take large quantities of alcohol for many years. During this time his diet had been inadequate. Dilated veins were present over the abdomen and there was severe bleeding from hæmorrhoids. Ascites and loss of weight were evident. He obviously had cirrhosis of the liver. While he was in hospital the blood prothrombin concentration fluctuated between 44 and 70% of normal. This fluctuation was irrespective of therapy with vitamin K by mouth or parenterally in addition to 200 g. of liver and 90 g. of dried brewers' yeast by mouth. There was no response to the daily injection of 5 c.cm. of crude liver extract (1 unit U.S.P. per 2 c.cm.) or nicotinic acid, 500 mg., given by mouth or parenterally.

GROUP 5

The lowered blood-prothrombin level drops despite therapy or remains below the level for hæmorrhage.—This group of patients have severe and widespread liver damage. Clinically they appear acutely ill and usually present hæmorrhagic manifestations—bleeding from the mouth, gums or nose, with cutaneous bruising. The blood-prothrombin concentration is in the "hæmorrhagic zone" and often continues to drop despite therapy. The liver seems incapable of producing prothrombin, since it is apparently severely damaged. The immediate prognosis is grave. Autopsy will reveal an acute hepatitis (acute yellow atrophy) or generalised malignant infiltration of the liver.

A male elevator operator,* aged 59, was admitted to Evans Memorial Hospital complaining of weakness and jaundice. After an acute respiratory infection four weeks before admission he lost his appetite, developed a brassy taste in his mouth and his urine became dark. There was no history of alcoholism or of taking drugs. He was deeply jaundiced, his liver enlarged, firm, smooth and tender, and his spleen palpable at the costal margin. The blood-prothrombin concentration was 29% of normal on the day of admission, and during the six days he was in the hospital the level dropped despite therapy. On the day of his death it had fallen to 5–10% of normal. Autopsy confirmed the clinical diagnosis of acute atrophy of the liver.

DISCUSSION

Wilson (1939), from a study of a group of patients with liver disease, in which he compared hippuric-acid excretion and plasma-prothrombin level, concluded that the blood-prothrombin level was as sensitive in the diagnosis of liver dysfunction as tests of hippuric-acid excretion. He found, however, no correlation between the blood-prothrombin levels and the blood-fibrinogen or the bromsulphalein and galactose-tolerance liver tests. In a comparative group of cases reported elsewhere (Kark et al. 1941) no correlation was observed between the blood-prothrombin level and single observations of hippuric-acid excretion in patients with liver disease, after correction by therapy of any coexisting deficiency of vitamin K.

In a report on 12 patients with hypoprothrombinæmia and hepatic disease (Kark and Souter 1940) it was pointed out that they did not respond to therapy with natural vitamin K or synthetic vitamin-K analogues. At that time it was suggested that this failure of response might have prognostic importance when considered along with the level at which the blood-prothrombin concentration was maintained in these patients. It also appears that the repeated observation of the blood-prothrombin level before and after therapy with vitamin K may give information of value in the differential diagnosis of intense jaundice when the results of other tests are equivocal (group 1). For example, if a patient with intense jaundice and well-marked hypoprothrombinæmia responds rapidly (within 48 hours) and completely (blood-prothrombin level returns to 90–100% normal), then the diagnosis is probably obstructive jaundice. On the other hand, if there is a well-marked hypoprothrombinæmia which does not respond to therapy with vitamin K, and especially if the blood-prothrombin level continues to drop after therapy (group 5), the immediate outlook for recovery is extremely poor. Conversely, if there is a response to therapy in an acutely ill patient with liver disease and hæmorrhagic hypoprothrombinæmia (cf. case 2, group 3), the immediate prognosis is not grave.

The extent of liver damage in the other three groups of patients can be told only after a longer period. Furthermore, single estimations of blood-prothrombin level are not likely accurately to assess the extent of the liver dysfunction which is present.

If any of the patients in groups 2, 3 or 4 require a surgical operation, either on the biliary tract or elsewhere, it is always necessary to restore their blood-prothrombin to a normal level and to maintain it there by pre- and post-operative transfusions of fresh blood or fresh plasma. The bleeding occasioned by surgical procedures on these patients may, by reason of prothrombin depletion, reduce an already low blood-prothrombin concentration to a dangerous level. If hæmorrhagic hypoprothrombinæmia develops in these patients they may bleed to death, since in such cases the loss of prothrombin by bleeding and the inability of the liver to produce sufficient prothrombin to make good this loss will perpetuate the hæmorrhagic state.

CONCLUSIONS

In patients with clinically evident liver disease five types of response to vitamin-K therapy have been observed.

In cases with intense jaundice in which the diagnosis is in doubt the rapid and complete return of a lowered blood-prothrombin level to normal after vitamin-K therapy favours a diagnosis of obstructive jaundice.

In cases of gross liver disease the failure of response to vitamin K, when the blood-prothrombin concentration is below 30–35% of normal, is indicative of advanced hepatic failure and is a grave prognostic sign.

In other types of cases with liver disease which respond incompletely or not at all to vitamin K, transfusion of fresh blood or fresh plasma is the only known therapeutic measure which can then increase the prothrombin concentration of the blood. In these cases this therapeutic measure should be employed, before and after operation, if any surgical procedure is necessary.

We wish to thank Dr. George R. Minot and Dr. William T. Salter for their criticism and advice.

PRESERVATION OF LIQUID COMPLEMENT SERUM

GEORGE MAXWELL RICHARDSON, D SC, PH D
(*Pathological Laboratory of the Ministry of Health*)

A PROPER technique for Wassermann tests should require that the pooled serum from at least three properly fed, healthy, adult male guineapigs is used as complement (Wyler 1929, Faber and Black 1938a, Eagle 1939, Kolmer 1939)) Any less exacting standard may lead to error Yet in war-time the weekly loss of three prime animals, if the serum is obtained by bleeding out, is an unwelcome extravagance Even if the serum is obtained by heart puncture as little demand as possible should be made on the animals In these circumstances, a simple means of preserving complement serum in the ordinary laboratory will be of much value

The most effective method known is to preserve the serum by drying it from the frozen state, provided that the drying is complete and the dried material is kept dry (Flosdorf et al 1935, 1940, Greaves and Adair 1936 1939) Yet the fact that success depends on the skill applied to a slightly involved technique makes the method less attractive to the ordinary worker Moreover, complement reconstituted from the dried material is *even less stable than is fresh complement* (Faber and Black 1938b) It can only be made up and kept satisfactorily if special preserving solutions such as those discussed below are used The purpose of this note is to outline some factors involved in preserving liquid complement, to discuss some recognised methods of preservation, and to describe some effective new methods

FACTORS CONTRIBUTING TO PRESERVATION

An inclusive explanation of factors involved in preserving liquid complement must take account of many seemingly unrelated facts Possibly the most puzzling of these has been the divergent results given by the same method of preservation on different occasions, or in the hands of different workers

The most popular method of preservation has been to freeze the serum solid in a freezing chamber or freezing mixture Methods for more moderate temperatures (0°–3° C) have been based on storing under carbon dioxide, or on the addition of hypertonic salt solution to the serum, a method which has been effectively modified by adding boric acid as well, presumably as a disinfectant Another modification depends on storing the salted serum in sealed containers (Glover 1933, Green 1938) Most workers have found that serum intended for preservation should be processed promptly, and Glover suggests that the value of sealing may be that it retains carbon dioxide in the serum The serviceableness of the various methods has been reviewed and examined by Kolmer and his colleagues (1919) and by Faber and Black (1938b)

Present work has shown that four factors are especially important in preserving liquid complement at room temperature or at 0°–3° C sterility, hypertonicity, pH and absence of specific destructive effects The chief shortcoming of previous methods has been an imperfect combination of these factors, especially with reference to pH The optimum pH for preservation at 0°–3° C is about 6 4 (as shown roughly by indicators), or at room temperature 6, and the optimum zone is a sharp one The stability of complement rapidly declines above pH 7 The variability of results with the same preserving technique may often express nothing more than a variable approach to the correct pH Sterile hypertonic complement serum should have a life of many months at 0°–3° C or room temperature, if the pH is correctly adjusted Consequences of these facts may be recognised from everyday experience

(*a*) Serum exposed to the air loses CO_2 erratically (the rate depending on such circumstances as warmth and shaking) and suffers an erratic alkaline drift towards pH 8, loss of activity in such serum will thus be erratic as well as rapid

(*b*) Loss of CO_2 can be retarded by low temperature, especially by freezing solid, and can be stopped by sealing in tubes, these procedures help to preserve fresh serum, but not serum which has already lost its CO_2

(*c*) Loss of CO_2 is accelerated by evacuation, vacuum dried serum will be especially unstable on reconstitution

(*d*) Loss of CO_2 can be reversed by storing under CO_2, alternatively, its destructive consequences can be avoided by replacing it with a non-volatile acid of suitable strength (pK 6–6 5),* these are suitable conditions for preserving complement

(*e*) *The rôle of boric acid is apparently complex since its* acid strength (pK 9 2) is insufficient to permit it to replace CO_2 (pK 6 1), its main effect is probably due to polymerisation to a more acid polymer (Thygesen 1938) Significant amounts of polymer are found only in concentrated solution, and this accords with the fact that only concentrated solutions are used for preserving serum (0 4–0 6 M) A secondary and variable effect may follow from the formation of acidic complexes with sugar alcohols or sugars Mannitol, for instance, strongly enhances the acidity of boric acid (Bell et al 1938), is widely distributed in plants, and is not easily metabolised after ingestion (Carr and Krantz 1938) Its presence in serum will vary with the quantity and type of diet, and thus the effect on the pH of boric acid serum will be variable Comparable effects will follow from the presence of other sugar alcohols The variable success of the boric acid method in different laboratories can thus be accounted for

SELECTION OF PRESERVING AGENTS

The choice of reagents to control sterility, hypertonicity, and pH is much restricted by specific destructive effects

Sterility—For various reasons few of the usual disinfectants can be used to control infection in complement serum Strong oxidising agents destroy complement (Ecker et al 1938), and highly coloured disinfectants are inconvenient Heavy metal salts, formaldehyde, and several phenols (trichlorophenol, 8-hydroxyquinoline, and sodium salicylate) were found to inactivate complement on prolonged exposure Merthiolate, phenyl mercuric nitrate, and boric acid were hæmolytic Sulphides, cyanides, and acid gases like sulphur dioxide would cause undesirable pH changes Thus only proflavines, sodium selenite and sodium azide were left for trial Azides resemble sulphides and cyanides in inhibiting cellular respiration (Keilin 1936), and the sodium salt in a strength of 0 01–0 05% will selectively inhibit a variety of aerobes growing on blood-agar plates (Snyder and Lichstein 1940) In this laboratory we have found it a better disinfectant for serum than selenite or proflavine at doses innocuous to complement

Sodium azide (NaN_3) is important as a disinfectant for serological uses because (*a*) it is neither hæmolytic nor destructive of complement at dilutions necessary to prevent visible infection of serum (M/80 = 0 08%), (*b*) it is chemically inert towards organic molecules of serological interest, and is stable in solution at neutral pH (only on substantial acidification is the poisonous hydrazoic acid set free, pK 4 5), (*c*) it is effective in considerable dilution and has ionic properties resembling sodium chloride—notable considerations in dealing with colloids These distinctive advantages are unfortunately offset by its toxicity, it is a powerful poison with effects resembling those due to cyanide (Smith and Wolf 1904) The dangerous dose is only 5–10 mg (Kavser 1928), and this is present in only 0 6–1 2 ml of the stock solutions described below (M/8) Obviously such solutions should not be handled by unskilled persons It may also be noted that the azides of heavy metals are detonators, though sodium azide is stable in solid form, it is probably best handled with non-metallic spatulas

Hypertonicity—Many salts have been recommended for increasing the tonicity of serum for preservation, but they have hitherto been studied without adequate control of pH, conflicting reports have been common (Faber

---

* In this note, pK is taken to mean the negative logarithm of the titration constant of the acid at an ionic strength equivalent to that of physiological saline

and Black 1938b) Work in this laboratory has not yet proceeded far, but it suggests that sodium salts of monovalent ions—e g , chloride—are more satisfactory than those of divalent ions of the dehydrating type—e g , sulphate, phosphate Since sodium chloride is the recognised diluent for serological work, it should be preferred for salting the complement, at least until strong reasons appear for using another salt The practicable hypertonicity will be simply that which can give, after dilution with water to the dose required for the test, a correctly isotonic solution

The pH—Most buffer mixtures which cover the pH region 6–7 include salts with divalent ions Preliminary work with phosphate buffers showed that such divalent salts give inferior results if used both to make the serum hypertonic and to control pH The best results followed from the lowest possible concentrations, tonicity being controlled by other means—e g , by adding sodium chloride

In experiments along these lines, buffer acids with pK values between 6 and 7 were chosen, and sufficient amounts added to samples of serum to bring the pH to about 6–6 2 (shown roughly by sulphonphthalein indicators) The samples were finally made up as 1 in 2 serum dilutions containing M/80 azide and sufficient sodium chloride to be 5 times isotonic and left at room temperature (15°–20°, C) in loosely stoppered tubes The control sample with only azide present became completely inactive within a fortnight, and the 5 × isotonic control without pH adjustment was inactive after five weeks Of the other samples, those adjusted to the above pH with M/50 NaH maleate (pK 6), M/40 cacodylic acid (pK 6 1), saturated CO_2 gas (pK 6 1), M/33 NaH glycerophosphate (pK 6 3), or M/25 NaH_2 phosphate (pK 6 6) have suffered no important change in titre in ten weeks Samples adjusted with hydrochloric acid were less satisfactory, while those with M/20 NaH sulphite (pK 6 7) were inactive in eighteen hours The phenomenal keeping power of salted complement adjusted to the proper pH with selected buffers has been confirmed on many occasions

PRESERVED COMPLEMENT IN THE WASSERMANN REACTION

The serviceability of the various mixtures for use in Wassermann tests by the Harrison-Wyler method (Wyler 1929) and by the recent modification of it (Richardson 1940) has been regularly under study

Complement preserved in acidified mixtures as above was found to be entirely satisfactory for tests by the Richardson modification, and for most tests by the Harrison-Wyler method Occasionally however, a non-syphilitic serum would be found in which a tendency to give a doubtful reaction by the Harrison-Wyler method, using fresh complement would be much accentuated by the acidified complement; the implications of this are being explored In the meantime it was thought that complement at the optimum pH for preservation ought not to be used directly for Wassermann tests An attempt to compromise between this pH and a safe pH for tests was made in early work It was found that complement treated with M/80 azide and M/8 phosphate of pH about 7 could be transmitted by post and still remain satisfactory in tests This important conclusion was confirmed by three pathologists—Dr J L Edwards, Major K E A Hughes, and Dr Robert Thomson to whom I am grateful for collaboration Nevertheless the stability of the product was not optimal, and attempts were next made to store the complement at its optimum pH but under such conditions that the pH automatically returned to less acid values merely on dilution This is the great advantage of the boric-acid method, since the polymer to which acidity is due practically disappears on dilution , but the method has the accompanying disadvantages of a variable pH during preservation, as already discussed, and of high concentrations of non-biological material These faults are remedied in the methods described below

DETAILS OF METHODS

Four solutions—A, B, and C for method 1, and C and D for method 2—are used

A. (*M/4 boric acid in saturated NaCl*)—Boric acid (H_3BO_3), 1 55 g , is dissolved in and made to 100 ml with saturated NaCl solution

B (*M/2 sorbitol, M/8 azide in saturated NaCl*)—Sorbitol ($C_6H_{14}O_6$ ½H_2O), 9 55 g , and sodium azide (NaN_3), 0 81 g , are made to 100 ml as above The very poisonous nature of sodium azide has been discussed

C (*M/8 azide in saturated NaCl*)—Sodium azide, 0 81 g , is made to 100 ml as above

D (*Saturated NaCl*)—A saturated solution of sodium chloride in water

In making solutions B and C, some NaCl may be precipitated It is assumed, however, that the final solutions have the same tonicity as saturated NaCl (5 4 M = about 36 × isotonic) Moderate change of temperature has little effect on the solubility of NaCl

Method 1—Eight volumes of serum are mixed with one volume of solution A and one volume of a mixture of B and C The suitable ratio of B to C may vary according to the source of the complement, but is likely to be about 1 1 (perhaps greater) The pH of the serum mixture should be about 6–6 5, as shown by a faint or negligible green tinge with bromothymol blue indicator and a distinct purple with bromocresol purple, while experience will show what conditions best suit the temperature chosen for preservation In the examples given, a 4 in 5 dilution of serum containing M/40 boric acid, M/40 sorbitol, M/80 azide, and 1 08 M NaCl will be obtained The tonicity will be 0 8 × isotonic with respect to serum and 7 2 × isotonic with respect to NaCl, or 8 × isotonic altogether. The method depends on the ability of boric acid and sorbitol to form an acidic complex whose acidity can be increased with increase in the sorbitol ratio On dilution the complex largely dissociates and the acidity disappears Similar use can be made of other polyhydric alcohols or sugars

Method 2—Eight volumes of serum are mixed with one volume of solution C and one of solution D The mixture is then stored under an atmosphere of CO_2 in a closed container On dilution and exposure to air the carbon dioxide disperses and the acidity disappears

Mixtures made by either method are kept in the dark and may be used as 1 in 10 complement dilutions simply by mixing 1 volume with 7 volumes of distilled water

The methods are satisfactory with stale serum provided the titre has been maintained and also, after appropriate changes, for reconstituting vacuum-dried serum Method 1 is suited to laboratories doing routine testing and lacking facilities for a supply of CO_2 Method 2 is suited to research laboratories needing complement with negligible adulteration , the 1 in 10 dilution has only M/640 (0 01%) sodium azide as adulterant and this is a salt closely resembling sodium chloride in ionic properties

SUMMARY

Successful preservation of the complement activity of hypertonic guineapig serum depends sharply on pH Sterile salted serum keeps for months at room temperature if brought to about pH 6 or, at 0°–3° C , to about pH 6 4 Sodium azide is the disinfectant of choice Methods are described for maintaining a suitably acid pH during storage, and restoring neutrality automatically on dilution They depend on the use of sorbitol-boric-acid complexes, or of carbon dioxide

I wish to thank the Dean of the London School of Hygiene and Tropical Medicine, and Prof James McIntosh of the Bland-Sutton Institute of Pathology, Middlesex Hospital, for hospitality during the course of this work , and Colonel L W. Harrison for his encouragement

PRESERVATION OF LIQUID COMPLEMENT SERUM

GEORGE MAXWELL RICHARDSON, D SC , PH D
(*Pathological Laboratory of the Ministry of Health*)

A PROPER technique for Wassermann tests should require that the pooled serum from at least three properly fed, healthy, adult male guineapigs is used as complement (Wyler 1929, Faber and Black 1938a, Eagle 1939, Kolmer 1939)) Any less exacting standard may lead to error Yet in war-time the weekly loss of three prime animals, if the serum is obtained by bleeding out, is an unwelcome extravagance Even if the serum is obtained by heart puncture as little demand as possible should be made on the animals In these circumstances, a simple means of preserving complement serum in the ordinary laboratory will be of much value

The most effective method known is to preserve the serum by drying it from the frozen state, provided that the drying is complete and the dried material is kept dry (Flosdorf et al 1935, 1940, Greaves and Adair 1936, 1939) Yet the fact that success depends on the skill applied to a slightly involved technique makes the method less attractive to the ordinary worker Moreover, complement reconstituted from the dried material is even less stable than is fresh complement (Faber and Black 1938b) It can only be made up and kept satisfactorily if special preserving solutions such as those discussed below are used The purpose of this note is to outline some factors involved in preserving liquid complement, to discuss some recognised methods of preservation, and to describe some effective new methods

FACTORS CONTRIBUTING TO PRESERVATION

An inclusive explanation of factors involved in preserving liquid complement must take account of many seemingly unrelated facts Possibly the most puzzling of these has been the divergent results given by the same method of preservation on different occasions, or in the hands of different workers

The most popular method of preservation has been to freeze the serum solid in a freezing chamber or freezing mixture Methods for more moderate temperatures (0°–3° C) have been based on storing under carbon dioxide, or on the addition of hypertonic salt solution to the serum, a method which has been effectively modified by adding boric acid as well, presumably as a disinfectant Another modification depends on storing the salted serum in sealed containers (Glover 1933, Green 1938) Most workers have found that serum intended for preservation should be processed promptly, and Glover suggests that the value of sealing may be that it retains carbon dioxide in the serum The serviceableness of the various methods has been reviewed and examined by Kolmer and his colleagues (1919) and by Faber and Black (1938b)

Present work has shown that four factors are especially important in preserving liquid complement at room temperature or at 0°–3° C sterility, hypertonicity, pH and absence of specific destructive effects The chief shortcoming of previous methods has been an imperfect combination of these factors, especially with reference to pH The optimum pH for preservation at 0°–3° C is about 6 4 (as shown roughly by indicators), or at room temperature 6, and the optimum zone is a sharp one The stability of complement rapidly declines above pH 7 The variability of results with the same preserving technique may often express nothing more than a variable approach to the correct pH Sterile hypertonic complement serum should have a life of many months at 0°–3° C or room temperature, if the pH is correctly adjusted Consequences of these facts may be recognised from everyday experience

(*a*) Serum exposed to the air loses CO_2 erratically (the rate depending on such circumstances as warmth and shaking) and suffers an erratic alkaline drift towards pH 8 , loss of activity in such serum will thus be erratic as well as rapid

(*b*) Loss of CO_2 can be retarded by low temperatures, especially by freezing solid, and can be stopped by sealing in tubes , these procedures help to preserve fresh serum, but not serum which has already lost its CO_2

(*c*) Loss of CO_2 is accelerated by evacuation , vacuum dried serum will be especially unstable on reconstitution

(*d*) Loss of CO_2 can be reversed by storing under CO_2, alternatively, its destructive consequences can be avoided by replacing it with a non-volatile acid of suitable strength (pK 6–6 5) ,* these are suitable conditions for preserving complement

(*e*) The rôle of boric acid is apparently complex since its acid strength (pK 9 2) is insufficient to permit it to replace CO_2 (pK 6 1) , its main effect is probably due to polymerisation to a more acid polymer (Thygesen 1938) Significant amounts of polymer are found only in concentrated solution, and this accords with the fact that only concentrated solutions are used for preserving serum (0 4–0 6 M) A secondary and variable effect may follow from the formation of acidic complexes with sugar alcohols or sugars Mannitol, for instance, strongly enhances the acidity of boric acid (Bell et al 1938), is widely distributed in plants, and is not easily metabolised after ingestion (Carr and Krantz 1938) Its presence in serum will vary with the quantity and type of diet, and thus the effect on the pH of boric acid serum will be variable Comparable effects will follow from the presence of other sugar alcohols The variable success of the boric acid method in different laboratories can thus be accounted for

SELECTION OF PRESERVING AGENTS

The choice of reagents to control sterility, hypertonicity, and pH is much restricted by specific destructive effects

Sterility —For various reasons few of the usual disinfectants can be used to control infection in complement serum Strong oxidising agents destroy complement (Ecker et al 1938), and highly coloured disinfectants are inconvenient Heavy metal salts, formaldehyde, and several phenols (trichlorophenol, 8-hydroxyquinoline, and sodium salicylate) were found to inactivate complement on prolonged exposure - Merthiolate, phenyl mercuric nitrate, and boric acid were hæmolytic Sulphides, cyanides, and acid gases like sulphur dioxide would cause undesirable pH changes Thus only proflavines, sodium selenite and sodium azide were left for trial Azides resemble sulphides and cyanides in inhibiting cellular respiration (Keilin 1936), and the sodium salt in a strength of 0 01–0 05% will selectively inhibit a variety of aerobes growing on blood-agar plates (Snyder and Lichstein 1940) In this laboratory we have found it a better disinfectant for serum than selenite or proflavine at doses innocuous to complement

Sodium azide (NaN_3) is important as a disinfectant for serological uses because (*a*) it is neither hæmolytic nor destructive of complement at dilutions necessary to prevent visible infection of serum (M/80 = 0 08%) , (*b*) it is chemically inert towards organic molecules of serological interest, and is stable in solution at neutral pH (only on substantial acidification is the poisonous hydrazoic acid set free, pK 4 5) , (*c*) it is effective in considerable dilution and has ionic properties resembling sodium chloride—notable considerations in dealing with colloids These distinctive advantages are unfortunately offset by its toxicity , it is a powerful poison with effects resembling those due to cyanide (Smith and Wolf 1904) The dangerous dose is only 5–10 mg (Kavser 1928), and this is present in only 0 6–1 2 ml of the stock solutions described below (M/8) Obviously such solutions should not be handled by unskilled persons It may also be noted that the azides of heavy metals are detonators , though sodium azide is stable in solid form, it is probably best handled with non-metallic spatulas

Hypertonicity —Many salts have been recommended for increasing the tonicity of serum for preservation, but they have hitherto been studied without adequate control of pH , conflicting reports have been common (Faber

---

* In this note, pK is taken to mean the negative logarithm of the titration constant of the acid at an ionic strength equivalent to that of physiological saline

traced back the history of my patients and found that in 6 breast cancer ran in the family All 6 patients had undergone operations for breast cancer and after the operation had had X-ray treatment by experts Male hormone was given to these patients to see whether when given over a long period it would inhibit severe metastasis and influence recurrences Naturally no prophylactic treatment could be applied before the first appearance of cancer, as can be done in mice—membership of a family in which cancer runs is no indication for prophylactic treatment Thus treatment could be started only when the normal mammary cells had already undergone cancerous change In 3 of the 6 there were no signs or symptoms of recurrence when male hormone was implanted ; in the other 3 metastases were present at that time. Of the following cases 4 have already been published in part (Loeser 1939, 1940).

CASE 1 —Married woman, aged 37 , no children Maternal aunt died from breast tumour Radical operation in Johannesburg in June, 1936, after X-ray treatment Recurrence above right clavicle in February, 1937 Histological examination revealed carcinoma I performed curettage in April, 1937, because of uterine hæmorrhage , hyperproliferation of the endometrium found During May–September, 1937, patient had testosterone propionate, 1500 mg , injected, resulting in amenorrhœa In December, 1937, testosterone propionate, 600 mg , was injected Symptoms of masculinisation appeared—enlargement of clitoris, hoarse voice, increased sexual urge, increased growth of hair, gain in weight These symptoms faded in June, 1938 In March, 1939, September, 1939, and March, 1940 testosterone propionate, 600 mg, was implanted again with the same result In November, 1940, the patient was free from symptoms or signs of cancer The voice remains hoarse

CASE 2 —Married woman, aged 42 , two healthy children, one miscarriage Paternal uncle died from cancer , grandmother died from breast tumour Radical removal of breast performed September, 1935, after X-ray treatment Recurrence in cicatrix on the left breast, March, 1936 , excision Second recurrence in armpit, October, 1936 ; histological examination confirmed carcinoma Curettage performed because of uterine hæmorrhages , hypertrophic endometrium found Between April, 1937, and January, 1938, testosterone propionate, 700 mg , injected December, 1938 to March, 1939, testosterone propionate, 600 mg , injected. In November, 1939, and June, 1940, implantations of testosterone propionate 600 mg , were made Signs of masculinisation followed as in case 1 In October, 1940, there were no signs or symptoms of cancer recurrence

CASE 3 —Spinster, aged 41 Mother died from breast tumour, illness lasting four years Radical operation on patient's right breast in Budapest in 1936, after three courses of X ray treatment, Supraclavicular recurrence in 1938, treated by X rays In June, 1938, patient consulted me because of pruritus vulvæ At that time she had no recurrence of breast cancer Between June and October, 1938, testosterone propionate, 700 mg , injected In January, 1939, testosterone propionate, 500 mg , implanted , implantation repeated in June, 1939 Masculinisation as in the other cases In December, 1940, there were no signs or symptoms of cancer

CASE 4 —Married woman, aged 60 , two children One sister had breast cancer For the past eight years patient had been treated with radium for carcinoma of the breast Multiple recurrences were treated by excision Metastases on both sides, supraclavicular and mediastinal Diffuse infiltration in right axilla with a suppurating ulcer the size of half a crown around the nipple The radiologist called in recommended morphine for pain , on account of the disseminated carcinosis no other treatment was carried out From July to October, 1939, testosterone propionate, 1850 mg was implanted The temporary result was a superficial swelling around the right nipple, accompanied by considerable reduction of the ulcer, softening of the hard infiltration in the armpit, and superficial swelling and pigmentation of the healthy breast Striking features were an increase in weight by 5 lb and obviously improved health , the pain along the right arm lessened considerably , the patient felt very well, walked about and looked after her household, whereas previously she had been confined to bed The improvement lasted only four months A new implantation could not be performed owing to lack of material The patient's weight dropped again and further decline could not be checked

CASE 5 —Married woman, aged 45 years ; no children. Sister had had breast cancer, and a nephew at the age of 18 was suffering from cancer of the testis and had recently been operated on Radical operation for cancer of the breast on the right side 1937, followed by much X-ray treatment in the next year She had two recurrences in the operation scar and a fresh recurrence in the axilla in July, 1939 From August to November, 1939, testosterone 1500 mg , was implanted At first patient showed similar striking symptoms of improvement to those in case 4, but there was no change in the consistency or size of the recurring tumour in the axilla, though it showed no enlargement , X-ray treatment dissipated this little tumour New recurrence in the armpit and left breast in April, 1940 As the patient had undergone temporary masculinisation after the implantation of testosterone, a trial was made of progesterone In July, 1940, progesterone, 300 mg , was implanted and daily doses of progesteral, 40 mg , by mouth were given up to a total of 2800 mg Menstruation stopped No result was obtained , metastasis in the liver with ascites was diagnosed

CASE 6 —Married woman, aged 28 , no children Paternal aunt died from breast tumour Two years ago operation was performed followed by X ray treatment because of breast cancer She had metastases in the mediastinum, with hoarseness Supraclavicular glands involved on both sides Radiologist refused further X ray treatment Progesterone, 400 mg , implanted in August, 1940, and for two months daily doses of progesteral, 40 mg taken by mouth There was no change in her condition She had amenorrhœa for approximately a year, and after the implantation amenorrhœa continued No improvement, further decline and death in November, 1940 The total amount of progesteral taken was 2400 mg

Cases 1, 2 and 3 had one common feature soon after radical operation and X-ray treatment they all developed recurrences , when treatment with male hormone was begun these were not present, for they had either been excised or had disappeared after X-ray treatment Clinically these patients were free from any sign of cancer when the injections or implantations of male hormone were begun But although they had shown recurrences soon after operation they remained free from recurrences and metastases for 3–4 years (cases 1 and 2) and 2½ years (case 3) after the hormone treatment It is now nearly five years since the operations were performed on all these patients and they are still in good health These patients will have to be observed for several more years before any final judgment can be reached, and it will be necessary to continue hormone treatment from time to time Even then it will be difficult to assume that the male hormone is responsible for the good result and the postponement of recurrences

Cases 4, 5 and 6 all had metastases at the time when hormone treatment was begun Cases 4 and 5 improved strikingly under implantation treatment for the first two or three months but the cancer itself remained unaltered and their decline could not be averted

DISCUSSION

There is a wide difference between inherited breast cancer in mice and carcinoma of the breast in women Virgin or castrated female mice of strains with high incidence of breast cancer seldom suffer from cancer of the breast Virgin or unmarried women acquire breast cancer more often than married women who have had children (Peller 1940) In my experiments the mice as well as the women showed an inherited susceptibility to breast cancer This susceptibility was further enhanced in the mice by œstrogenic substances developed in response to forced breeding as a result of which the mammary gland was exposed without interruption to hormonal irritation The same cannot be said of the patients , 4 of them had never had a child, and there is no reason to assume that their mammary glands had been exposed to any irritation by œstrogenic substances Whether they produced abnormally high amounts of these substances in their tissues cannot be said But the antagonist of œstrogens was introduced into their circulation, and it is my impression that it was not the antagonistic action alone but the alteration in the patient's constitution—the masculinisation—which had an effect. The crescendo of masculinisation coincided with improvement in their condition ; the diminuendo with progress of the disease

MAMMARY CARCINOMA

RESPONSE TO IMPLANTATION OF MALE HORMONE AND PROGESTERONE

ALFRED A LOESER, M D. BERLIN, L R C P E

(Department of Biometry, University College, London)

A HIGH percentage of certain strains of mice die from cancer of the breast and some women seem to have an inherited susceptibility to the disease Apart from inherited susceptibility, one of the carcinogenic factors which may transform a normal cell into a cancerous one is said to be a surplus of œstrogenic substances in the body It appeared, therefore, worth while to try to counteract the female hormone by male hormone

Lacassagne (1939), Raynaud (1939), Murlin (1939), and Nathanson and Andervont (1939) have published papers on the same subject, but they never used the implantation method—they made injections with male hormone Sometimes they injected the mice at a very early age before they had litters (between the 1st and 21st day of life), and none of them treated the mice after the age of 4–4½ months If a mouse is treated with male hormone soon after birth there is a risk that the mammary gland will be prevented from developing Male hormone in big doses causes an atrophy of the mammary gland as well as of the ovaries, and the suppression of the ovarian function may also be secondary to pituitary inhibition No details of the changes in the different glands can be described in this paper, but the results of a long-continued action of testosterone on these glands are well known

All the observers mentioned showed that testosterone protects from cancer of the breast a high percentage of mice of the strain I used in my experiments Murlin influenced the growth and metastasis of the transplanted Brown-Pearce epithelioma by urinary androgens and considerably reduced severe metastasis and mortality, especially when the injections were begun before the inoculation of the tumour The workers quoted tried to counteract inherited susceptibility to cancer by injecting male hormone, and succeeded to some extent where they injected the mice at a very early age But they undoubtedly altered the constitution of a female mouse if they injected the male hormone so early, and at the end of the course there was only a rudimentary mammary gland, or a gland which had never properly developed It is not surprising therefore that these mice did not develop cancer of the breast, since the œstrogenic factor could not be formed while the ovaries remained atrophic, and these mice were never wholly female

In the following experiments I used the implantation method in order to maintain a permanent source of counteracting hormone in the tissues It is perhaps worth comparing the results in strains of mice with a very high familial incidence of breast cancer and those obtained in women suffering from breast cancer who had a high familial incidence of the disease Unfortunately the number of animals and patients who were treated and observed over several years was small The animal experiments took place between February, 1939, and September, 1940 The war prevented me from breeding further generations of mice It was also difficult to keep track of the patients over a sufficiently long period Many of the treated patients left London before my observations were concluded, and only a small number could therefore be used for the purpose of this inquiry

MOUSE EXPERIMENTS

Mice of Strong A strain were used They show a very high incidence of breast cancer, and according to Bittner (1939) up to 83% die from breast cancer when they are eleven months old and have had several litters I had at my disposal 354 mice born in the laboratory but only 65 were bred and used either for implantation or as controls Out of these 65 mice, only 22 remained for investigation over a period of thirteen to sixteen months, 43 died from intercurrent disease or failed to have three litters

Of the 22 remaining mice 10 (nos 1–10) had testosterone propionate implanted and 12 (nos 11–22) were controls Each of them had three litters, the 10 treated mice having 165 offspring altogether, and the controls 189. Every three to five weeks 7–8 mg of testosterone propionate was implanted subcutaneously in tablet form, being embedded in the subcutaneous fat of the back of mice nos 1–10 After three or four weeks the small tablet was usually absorbed

Of the 12 control mice 9 died from cancer of the breast (see table) They usually showed the first sign of cancer between the tenth and eleventh month and on an average it took a month from the beginning of the disease for them to die Mouse no 20 died at 10 months of intercurrent disease Of the 10 implanted mice 4 died from cancer Mouse no 4 had no cancer when it died from an intercurrent disease at fourteen months It was found that none of the mice who lived for more than fifteen or sixteen months died from cancer All the mice of this strain which had no cancer by the age of twelve or thirteen months died from some other cause, the age at death being between sixteen and eighteen months Altogether 5 of the treated mice and 2 of the controls survived, 4 of the treated mice and 9 of the controls died of cancer, 1 treated mouse and 1 control died from other causes

RESULTS OF IMPLANTATION OF TESTOSTERONE PROPIONATE IN MEMBERS OF A STRAIN OF MICE SUSCEPTIBLE TO MAMMARY CANCER

No	TREATED MICE (Testosterone propionate 7–8 mg in each implant)			No	CONTROL MICE
	Age at first implant (months)	No of implant	Result		Result
1	4½	7	Living, 15 mths, no cancer	11	Died cancer, 12 mths
2	5½	7	Living, 15 mths, no cancer	12	Died cancer, 13 mths
3	6	7	Died cancer, 14 mths	13	Died cancer, 14 mths
4	5½	7	Died, 14 mths, no cancer	14	Died cancer, 13 mths
5	8	3	Died cancer, 10 mths	15	Died cancer, 12 mths
6	8	5	Living, 16 mths, no cancer	16	Living, 16 mths, no cancer
7	5½	4	Living, 15 mths, no cancer	17	Died cancer, 13 mths
8	8½	5	Died cancer, 12 mths	18	Died cancer, 12 mths
9	8	4	Living, 15 mths, no cancer	19	Living, 15 mths, no cancer,
10	9	4	Died cancer, 13 mths	20	Died, 10 mths, no cancer
				21	Died cancer, 12 mths
				22	Died cancer, 12 mths

If we compare the 5 mice who did not develop cancer after the implantation with the 4 mice who did so in spite of implantation, we find that 3 of the former had received implants before the age of six months, whereas all the latter received implants at six months or even later. The younger a mouse the more implants can be made, thus the young mice received 7 implants The fewer the implants the more limited the chance of protection In some of the mice who developed cancer fresh implants were made even after the first appearance of the growth, but no beneficial effect could then be observed Histological examination of the tumours revealed no difference in the treated and control cancerous mice

I made no implantations until the mice had had three litters, when forced breeding had produced œstrogenic substances without interruption for at least the first four and a half months of their lives Thus not only was the hereditary factor acting but a surplus of œstrogenic substances had also stimulated the breast Of the 4 mice which were implanted before the first half of their precancerous life was over, 3 appeared to be protected from cancer for fifteen months and more, whereas of 6 mice implanted nearer to the date when breast cancer in this strain usually appeared, 4 were not protected

CLINICAL TRIALS IN WOMEN

The mamma is an organ in which there is a high familial incidence of cancer, often restricted to the immediate female relatives of the woman suffering from breast cancer, as the statistical investigations of Wassink (1936) in Holland and of Waaler in Norway have shown I

THE LANCET

LONDON. SATURDAY, DECEMBER 6, 1941

EGG OR SCORPION?

EARLY in 1939 SIR ARNOLD WILSON and Prof. HERMANN LEVY published their first volume on our law of workmen's compensation surveying the historical origins, Parliamentary debates and departmental inquiries The war, which has broken their admirable partnership and delayed their second volume now published[1] must not be pleaded as an excuse for deferring study of their conclusions on the admitted need of reform War means extended hours in factories a quickened industrial tempo, more fatigue less experienced workers (some of them long unemployed) new machinery, processes and materials involving unknown risks of accident and injury These conditions are in part familiar in times of prosperity, war adds personal anxieties, air-raid dangers and the inconvenience of the blackout

After leading them in industry, Britain has lagged behind other countries in her scheme of industrial compensation Distrusting bureaucracy we have refused to contemplate large-scale official administration We leave this great social activity to the private enterprise of the insurance companies and to the judicial impartiality of the county courts. The courts are swift and their proceedings are reported but there is a lack of uniformity, a settlement passed by the judge or registrar of one court would be rejected it is said by that of another Hence the demand for a Workmen's Compensation Commissioner Afraid of interfering with the individual control of business we have not even insisted upon compulsory insurance of employers (except in mining) though we now insist upon it for motorists We hesitate to create a "State monopoly" of occupational insurance because it would be so costly, yet an insurance company pays out only 60 per cent of its earned premiums in awards to incapacitated workmen about 9 per cent being consumed in commissions and 32 per cent in management expenses What would we say if a banker, taking our money on deposit, informed us that about 40 per cent of it would be absorbed by expenses? The companies do not concern themselves with accident prevention The insured employer has no incentive to diminish the risks The standard of safety is said to be highest in those great undertakings which carry their own insurance

Hesitating to fetter freedom of contract we have left the law too loose The all too attractive bait of the lump-sum agreement is dangled It looks like a nest-egg, but has a sting in its tail The injured man, be it recalled, can choose between three legal remedies First comes the common-law claim for damages, based on some breach of duty on the employer's part and complicated by the defence of "common employment" which eminent judges have called fantastic Next comes the Employer's Liability Act with its own special technicalities seldom used but still to be considered Lastly the Workmen's Compensation Act imposes liability irrespective of negligence by either side Its sweeping provisions were meant to simplify awards, but the notorious words "accident arising out of and in the course of the employment" have multiplied the litigation which the statute was to avert Faced with the choice of remedy, the workman may have no trade-union to advise him The insurance company will naturally seek a settlement which suits itself Last October the Master of the Rolls criticised "an act of the shabbiest description" discreditable to such companies' reputation for decent, humane and reasonable behaviour; he warned them not to take advantage of an injured man, nearly always a working man who might be suffering from shock, by putting before him a form when he had no-one near to advise him and then afterwards contending that because he had signed the form, he had precluded himself from making a more advantageous claim Does it pass the wit of man to substitute one foolproof remedy for the workman's triple choice and to develop our hospital services and other remedial facilities as part of a coördinated scheme of industrial compensation and State health insurance[2] We have no answer to the charge that the law of workmen's compensation fails to do anything for the medical care of the injured or unfit man for his physical or vocational rehabilitation and his reabsorption into industry We are backward in fracture clinics If the general practitioner cannot provide the best diagnosis and treatment of the man's injury in his own home, the general hospital may also fall short, moreover it seldom keeps the patient long enough Figures are offered to show that incapacity is far more prolonged, and permanent disablement far more likely, when the patient is not treated in a proper clinic This brings us to problems of staffing the appointments in surgery The Delevingne Committee report repeated somebody's blunt dictum that "there is no money in fractures" as far as surgical practice outside the hospital is concerned. If the fracture clinic is to be well organised, something must be done to offer the surgeon-in-charge a post which is pecuniarily attractive Mention of the medical referee raises other problems, there are the old doubts of his independence and of the value of the final decision of a single arbiter, especially if he sometimes appears as an expert witness in the court of an adjoining district Medical examination itself moreover, seems to cause the workman misgivings He goes before the insurance company's doctor like a plaintiff about to suffer cross-examination, the atmosphere is controversial, there are implied suspicions of malingering There is no certainty that he will be allowed to have his own doctor present He will inevitably dislike examination by a doctor known to have given evidence to the disadvantage of other injured workmen As for the place of the examination will it be his own home or his own doctor's consulting-room or will it be a solicitor's office?

These may be small points compared with so fundamental a matter as our failure to furnish continuity and uniformity of treatment from first aid to rehabilitation, but if we want the blessings of industrial peace and a contented society, we must remove the sense of injustice And for this purpose there can be no better preparation than a study of this new work by SIR ARNOLD WILSON and Professor LEVY WILSON'S courage of thought (as conspicuous

---

[1] Workmen's Compensation vol II (Need for Reform) Sir Arnold Wilson M P and Prof Hermann Levy London Humphrey Milford Oxford University Press. Pp 363 18s

Progesterone can also be regarded as antagonistic to the follicular hormone In my cases no effect of progesterone on the cancer cells was observed Progesterone acts quicker when given by mouth than when implanted, and as it was only applied in hopeless cases no definite conclusions should be drawn, but it might be worth trying it in still more massive doses in cases which—like my cases 1, 2 and 3—are free from cancer at the time of treatment

Incomplete as this series is, I hope it may encourage others to try out the idea and perhaps to implant testosterone or progesterone in cases of breast cancer at the time when the radical operation is performed It may be implanted in the tissues of the operated breast whether postoperative X-ray treatment is given or not, and the implant should be repeated as soon as the signs of masculinisation disappear The effect of testosterone is always temporary, and may be compared with a temporary sterilisation, which in contrast to X rays acts on every tissue of the cancerous body instead of locally I suggest that testosterone propionate, 700 mg, should be injected over two months I have called this the hormone atrophy dose (H A D) for the endometrium, since it temporarily sterilises any healthy woman and makes the endometrium atrophic (Loeser 1940) It is better to implant testosterone propionate, 500 mg, than to inject 700 mg, since the implant has a more lasting effect

SUMMARY

On the assumption that excess of œstrogenic substance is a factor in producing cancer of the breast, an attempt was made to counteract this effect by implanting male hormone

In mice of a strain showing a very high incidence of breast cancer testosterone propionate was implanted subcutaneously in 10 every three to five weeks while 12 acted as controls Implantation was not begun until the mice had had three litters In the treated group 4 and in the controls group 9 died of cancer

In 6 women with a family history of breast cancer who had had their breasts amputated for carcinoma, testosterone propionate or progesterone or both were repeatedly implanted and in 2 progesteral was also given by mouth In 3, recurrences were present at the time of implantation, and though 2 of these improved temporarily in general health, the progress of the cancer was not checked In 3 no recurrences or metastases were present at the time of implantation, and none has appeared in the subsequent five years

It is suggested that male hormone should be implanted in the operation site when the breast is removed for carcinoma, and implantation should be repeated when signs of masculinisation disappear

I wish to thank Prof J B S Haldane for allowing me to work in the Department of Biometry at University College, London, Dr H Gruneberg and Dr P A Gorer for giving me advice on breeding mice, Miss M Watson my assistant and the Schering Corporation of New York and Organon Laboratories for supplying testosterone and progesterone tablets

Reviews of Books

Lipidoses Diseases of the Cellular Lipid Metabolism

SIEGFRIED T THANNHAUSER, M D, Ph D, formerly professor of medicine, University Clinic, Freiburg, associate professor of medicine, Tufts College medical school London Humphrey Milford, Oxford University Press Pp 370 30*s*

MOST of our knowledge of this group of metabolic disorders has accumulated during the last twenty years, a period covered by Professor Thannhauser's contribution of the section on lipoid diseases to the "Oxford Loose-Leaf Medicine" The publication in book form of this monograph by one who has contributed so much to this particular branch of medicine will be welcomed by all interested in the lipoidoses The volume, which is well edited by Prof H A Christian of Harvard, is abundantly illustrated and embodies full records of cases observed by the author Appropriately enough, the section on xanthomatosis occupies most of the book, it embraces 12 primary types divided into hypercholesteræmic and normocholesteræmic groups, and 8 other types Gaucher's disease and Niemann-Pick's disease are fully considered in separate sections

The author has no doubt that the primary lipoidoses are manifestations of abnormal intracellular metabolism in the reticular and histiocytic cells of the organism, supporting this concept with convincing biochemical and experimental evidence He regards an imbalance of intracellular lipoidases as the fundamental disturbance The research worker will reap a rich harvest from the 1076 references which are conveniently arranged at the end of each section

Parenthood Design or Accident?

(4th ed) MICHAEL FIELDING London Williams and Norgate Pp 259 2*s* 6*d*

THIS excellent little book on birth control and related problems needs no introduction either to the medical profession or to the public In this edition recent research work on spermicides is included, the description of the technique of well-established and desirable methods has been rewritten in the light of modern experience, dangerous, ineffective, emergency and experimental methods are fully discussed, so also is the safe period It would be difficult to find a more lucid and concise description, or a more helpful evaluation, of this much publicised method of family *limitation* The sections on the sociological, ethical and legal aspects of contraception remain materially unchanged The appendices include lists of birth-control clinics in the United Kingdom and of approved and reputable appliances and chemicals There is also a short bibliography, glossary and index

Arthritis and Allied Conditions

(2nd ed) BERNARD I COMROE, M D, F A C P London Henry Kimpton Pp 878 42*s*

THIS is a large book but not too large, for arthritis and various conditions loosely termed rheumatic occupy a considerable part of medical practice here as well as in Philadelphia In fact Dr Comroe often compresses the result of much study (there are references to over two thousand original papers) into a small space General practitioners, as well as physicians especially interested in chronic rheumatism, will find much to interest them and to help them in their choice of therapy, though they will probably use the book more for reference than for light reading on dark evenings The illustrations are good and more profuse than in the first edition, while new chapters have been added and many old ones rewritten Curiously, the paging of the sections of each chapter is given in the table of contents, not the paging of the chapters themselves, but the index is full

Out of the Test Tube

(3rd ed) HARRY N HOLMES, Ph D New York Emerson Books Inc Pp 305 $3

FEW of us without special knowledge of the subject ever pause to consider the material benefits conferred by chemistry upon mankind In his expanded and revised edition Dr Holmes gives a vigorous account of what the chemist, working in divers spheres, has done, is doing and will do for us Our food, tools and clothing, our medicines, means of transport and weapons of war are only a few of the accepted accompaniments of modern life which are profoundly influenced by chemistry It is depressing to reflect on how high explosive has been largely diverted from its proper purpose of quarrying rock and so liberating slave-labour, or to realise that profit-making rather than philanthropy has been a prime motive of chemical research But we shall change all that in the brave new world after the war

THE LANCET

LONDON SATURDAY, DECEMBER 6, 1941

EGG OR SCORPION?

EARLY in 1939 Sir ARNOLD WILSON and Prof HERMANN LEVY published their first volume on our law of workmen's compensation, surveying the historical origins, Parliamentary debates and departmental inquiries The war, which has broken their admirable partnership and delayed their second volume, now published [1] must not be pleaded as an excuse for deferring study of their conclusions on the admitted need of reform War means extended hours in factories, a quickened industrial tempo more fatigue, less experienced workers (some of them long unemployed), new machinery, processes and materials involving unknown risks of accident and injury These conditions are in part familiar in times of prosperity, war adds personal anxieties, air-raid dangers and the inconvenience of the blackout

After leading them in industry, Britain has lagged behind other countries in her scheme of industrial compensation Distrusting bureaucracy, we have refused to contemplate large-scale official administration We leave this great social activity to the private enterprise of the insurance companies and to the judicial impartiality of the county courts. The courts are swift and their proceedings are reported but there is a lack of uniformity, a settlement passed by the judge or registrar of one court would be rejected, it is said by that of another Hence the demand for a Workmen's Compensation Commissioner Afraid of interfering with the individual control of business, we have not even insisted upon compulsory insurance of employers (except in mining) though we now insist upon it for motorists We hesitate to create a "State monopoly" of occupational insurance because it would be so costly, yet an insurance company pays out only 60 per cent of its earned premiums in awards to incapacitated workmen about 9 per cent being consumed in commissions and 32 per cent in management expenses What would we say if a banker, taking our money on deposit, informed us that about 40 per cent of it would be absorbed by expenses? The companies do not concern themselves with accident prevention The insured employer has no incentive to diminish the risks The standard of safety is said to be highest in those great undertakings which carry their own insurance

Hesitating to fetter freedom of contract we have left the law too loose The all too attractive bait of the lump-sum agreement is dangled It looks like a nest-egg, but has a sting in its tail The injured man, be it recalled, can choose between three legal remedies First comes the common-law claim for damages, based on some breach of duty on the employer's part and complicated by the defence of "common employment" which eminent judges have called fantastic Next comes the Employer's Liability Act with its own special technicalities seldom used but still to be considered Lastly the Workmen's Compensation Act imposes liability irrespective of negligence by either side Its sweeping provisions were meant to simplify awards, but the notorious words "accident arising out of and in the course of the employment" have multiplied the litigation which the statute was to avert Faced with the choice of remedy, the workman may have no trade-union to advise him The insurance company will naturally seek a settlement which suits itself Last October the Master of the Rolls criticised "an act of the shabbiest description" discreditable to such companies' reputation for decent, humane and reasonable behaviour, he warned them not to take advantage of an injured man, nearly always a working man who might be suffering from shock, by putting before him a form when he had no-one near to advise him and then afterwards contending that because he had signed the form, he had precluded himself from making a more advantageous claim Does it pass the wit of man to substitute one foolproof remedy for the workman's triple choice and to develop our hospital services and other remedial facilities as part of a coordinated scheme of industrial compensation and State health insurance? We have no answer to the charge that the law of workmen's compensation fails to do anything for the medical care of the injured or unfit man for his physical or vocational rehabilitation and his reabsorption into industry We are backward in fracture clinics If the general practitioner cannot provide the best diagnosis and treatment of the man's injury in his own home the general hospital may also fall short, moreover it seldom keeps the patient long enough Figures are offered to show that incapacity is far more prolonged and permanent disablement far more likely when the patient is not treated in a proper clinic This brings us to problems of staffing the appointments in surgery. The Delevingne Committee report repeated somebody's blunt dictum that "there is no money in fractures" as far as surgical practice outside the hospital is concerned If the fracture clinic is to be well organised, something must be done to offer the surgeon-in-charge a post which is pecuniarily attractive Mention of the medical referee raises other problems, there are the old doubts of his independence and of the value of the final decision of a single arbiter, especially if he sometimes appears as an expert witness in the court of an adjoining district Medical examination itself, moreover, seems to cause the workman misgivings He goes before the insurance company's doctor like a plaintiff about to suffer cross-examination, the atmosphere is controversial, there are implied suspicions of malingering There is no certainty that he will be allowed to have his own doctor present He will inevitably dislike examination by a doctor known to have given evidence to the disadvantage of other injured workmen As for the place of the examination will it be his own home or his own doctor's consulting-room or will it be a solicitor's office?

These may be small points, compared with so fundamental a matter as our failure to furnish continuity and uniformity of treatment from first aid to rehabilitation, but, if we want the blessings of industrial peace and a contented society, we must remove the sense of injustice And for this purpose there can be no better preparation than a study of this new work by Sir ARNOLD WILSON and Professor LEVY WILSON'S courage of thought (as conspicuous as the physical gallantry with which he met his death), his gift of handling the statistics which in this subject are none too adequate, his industry and his astounding facility of quotation are here exemplified Linked, not for the first time, with the solid abilities of the collaborator who survives him, they add one more to the series of reports which, like those of Chadwick in the field of poor law and public health a century ago, compel social reform

NEW DRUGS IN PROTOZOAL INFECTIONS

In 1935 some continental workers recorded that the drug Synthalin (decamethylene-guanidine dihydrochloride) exerted a slight therapeutic action on certain pathogenic trypanosomes in mice They ascribed this action to hypoglycæmia produced by the drug, an adequate supply of sugar being essential to the metabolism of trypanosomes, and not to a direct action of the compound on the parasites Warrington Yorke and his collaborators thought that a degree of hypoglycæmia sufficient to affect the trypanosomal infections would be incompatible with the life of the host, and decided to investigate the subject further They found that, in vitro, synthalin exerted a direct and powerful trypanocidal action, a dilution of only 1 in 100 million destroying all the trypanosomes in a suspension of nutrient medium within 24 hours at 37° C They further found that the degree of hypoglycæmia produced in the normal animal by synthalin in therapeutic dosage is not pronounced The discovery that synthalin has a direct lethal action on certain trypanosomes opened up a wide field of biological and chemical investigation into the chemotherapeutic value of drugs of this and allied series in protozoal infections of man and of animals This inquiry was followed by the preparation and trial of many compounds, of which three, produced by Ewins of May and Baker Ltd, have been shown by Yorke and his co-workers to possess considerable therapeutic promise These are all diamidine compounds and are diamidinostilbene, diamidinodiphenoxypentane and diamidinodiphenoxypropane Cases of human sleeping sickness, of human visceral leishmaniasis and of babesiasis in domesticated animals have now been successfully treated with these compounds, and information is being accumulated that not only are these drugs therapeutically active in such conditions but that in some of them they are superior to any remedy hitherto employed This is more particularly the case in the Mediterranean and Sudan forms of visceral leishmaniasis, or kala azar, conditions with a very high mortality which are notoriously resistant to the antimony treatments normally effective in the Indian form of the disease

Some figures collected by Stephenson,[1] showing the results of antimony treatment of cases of Sudan leishmaniasis, with others collected by Kirk and Sati,[2] showing those of treatment with the diamidines, illustrate this point Stephenson saw 73 cases of Sudan leishmaniasis between the end of 1937 and the middle of 1939 Of these, 19 were admitted moribund and died before treatment could be begun Of the remaining 54 cases, 25 died in hospital and 22 were discharged as presumably cured, but 11 of these subsequently died Another 7 left hospital before completion of treatment and 6 of these later died The standard treatment was a course of 4 8 g Neostibosan, followed by a full course of tartar emetic, and in some cases by further courses of these drugs or of Anthiomaline The total result was that of 54 cases treated only 12 were alive in January, 1940 Kirk and Sati treated 49 cases of Sudan leishmaniasis with the diamidines, of whom 8 died Of these 8, 5 were moribund on admission, and 1, when progressing well, broke out of hospital on a debauch and died within 48 hours Of the 43 cases which completed treatment 41 (95%) were provisionally regarded as cured These results compare most favourably with those obtained with the antimonials Cases treated by other workers in Palestine and elsewhere, both of the Indian and of the Mediterranean forms of kala azar, show that the diamidines may effect a cure where antimony has previously been given and proved ineffective In Africa these drugs are being tested on cases of human trypanosomiasis and have been found rapidly to produce sterilisation of the peripheral blood, early cases, as a result, are cured by them So far there is inadequate information as to their effect on late cases with involvement of the central nervous system In the veterinary field the diamidines have shown much promise in the treatment of the various forms of babesiasis, a condition responsible for great economic loss among dogs and domestic stock The diamidines may be given to man in doses ranging from 0 5 to 2 mg per kg body-weight, either intravenously or intramuscularly Owing to their greater solubility, diamidinodiphenoxypropane and diamidinodiphenoxypentane are more suitable for intramuscular injection than is the less soluble diamidinostilbene The drugs may be given daily or on alternate days until 30, or even 60 or 90, injections have been administered No serious accidents have so far been recorded, although certain immediate effects lasting about half an hour occur owing to a dramatic fall in blood-pressure These are more pronounced when the intravenous route is employed, and vary from headache and dizziness with a rapid pulse, sweating and retching with occasional vomiting, to alarming symptoms in a small number of cases, where there may be syncopal-attacks with temporary unconsciousness These symptoms are all transient and last but a short time, and no permanent after effects have been observed

THERAPEUTIC RESEARCH LIMITED

Freedom and opportunity, as Sir Henry Dale reminded the Royal Society on Monday, provide the conditions for the highest type of research The quality of research is in fact determined by the character of those engaged in it and not by organisation or by the source of endowment Stated thus the proposition sounds self-evident Yet there is no denying the justice of the reproach made by the promoters of the new Therapeutic Research Corporation[1] that there has existed in the past a diffidence on the part of some academic research workers in this country to ally themselves wholeheartedly with the researches of industrial firms, or the rightness of the corporation's aim to establish closer liaison between industry and the research laboratories of the universities It is only a couple of months ago that we remarked in these columns "If ever there was a case for open and full cooperation here is one." Moreover the die was cast when in January, 1937, two medical men holding important academic positions became trustees under Sir Henry Wellcome's will for the allocation to medical research of the profits of a great manufacturing and trading organisation. The new approach is less surprising when one reflects that the research staffs of the most individualistic concerns have fraternised freely in the past. Knowledge has an instinctive urge to companionship and the most jealously guarded secrets have been those with nothing substantial to conceal. There is a little more to it than a common research pool. Five laboratories—and there is nothing to prevent others coming in—with highly trained staff and elaborate equipment will now be able to concentrate on the solution of any new problem. And, perhaps the best feature of all, any new drug which may be discovered will not be monopolised by one member of the corporation. This will facilitate the known intention of the Medical Research Council to undertake chemotherapeutic research on a much larger scale in the future. Clearly there is no room here for the relaxation of the rigid standards of true science in favour of policy or propaganda which the President of the Royal Society regards as a danger to be foreseen and resisted.

CADMIUM POISONING

If we know cadmium at all most of us would recall its brilliant sulphide, which as Cadmium Yellow is familiar in the paint-box and was thrown down by H_2S from acid solution in our analytical tables. It occurs in nature as the sulphide in association with zinc ores, chiefly in Scotland (as "greenockite"), in Czechoslovakia and in Pennsylvania. It is a bluish-white metal which takes a high polish, and can easily be deposited electrolytically from a cyanide bath. Lately it has come to be increasingly used for plating in place of silver, nickel and chromium, and it is this that has led to trouble. There have been instances of poisoning from the inhalation of dust containing cadmium in zinc works, but most of the recorded cases have arisen from the unwise use of cadmium-plated vessels containing foodstuffs, because cadmium is readily corroded by acetic, tartaric, citric and lactic acids and therefore by foodstuffs containing vinegar, fruit acids and the like.

On another page Dr A T W Powell recalls eight cases of poisoning resulting from the preparation of "lemonade" ices in refrigerator trays replated with cadmium. In his report for 1935 the Chief Medical Officer of the Ministry of Health recorded the poisoning of three people by cadmium falling into their food from the reflector of an electric cooker. Dr Powell also draws attention to 208 cases of cadmium poisoning reported in the U S Navy,[1] where foodstuffs had been in contact with cadmium-plated utensils for 1½–14 hours. It was found there that anything over 15 parts per million of cadmium might produce symptoms of poisoning, and some of the navy men had drunk lemonade containing 100 p p m. A few months ago Frant and Kleeman[2] reported five outbreaks in the United States, involving some 50 people in all. One of these, in which at least 29 school-children were affected, was traced to cadmium contamination of popsicles—flavoured ices frozen on a stick. Here too the popsicle moulds had been replated with cadmium. In these cases the symptoms are those with which the wise student defeats his examiner when asked for the symptoms of irritant poisoning—vomiting, diarrhœa, abdominal pain, and the symptoms and signs of dehydration—and the violent evacuation seems to prove effective, for fatal cases are rare. In the popsicle epidemic all the children recovered completely in 5–6 hours. Cases due to inhalation are less common but may be more deadly. In 1858 Sovet[3] reported poisoning in three domestic servants who inhaled the dust when polishing silver with cadmium carbonate. Here the symptoms were collapse, cramps in the legs, headache, a feeling of constriction in the throat, continuous vomiting, and blood-stained diarrhœa with colic. One of the three also developed pneumonia and nearly died. Sir Thomas Legge, in his factory report for 1923 (p 74), reported poisoning in an engineer and two workmen who inhaled fumes while melting down ingots of cadmium in an ill-ventilated factory. The engineer died, and the autopsy showed congestion of the larynx, trachea, bronchi, stomach and intestine, with fatty infiltration of the heart and liver, and congestion of the spleen and kidneys. Curiously enough, chemical analysis of the viscera revealed no trace of cadmium. Chronic poisoning has been extensively studied in animals, but seems to be rare in man. Stephens,[4] however, has reported 9 cases of chronic poisoning. One was an elderly zinc smelter who had received compensation for plumbism, but at autopsy he was found to have chronic interstitial nephritis and cardiac hypertrophy, and his liver contained nearly a grain of cadmium to the pound. It seems, therefore, that despite the severity of the local action on the stomach, a certain amount of cadmium may gain access to the body tissues.

In the factory where ores containing cadmium are smelted, or wherever dust or fumes of cadmium may be in the air, prevention must depend on adequate ventilation, supported when necessary by masks. But for the commoner danger prophylaxis is simpler: cadmium plating, however desirable it may be for motor-car parts, must not be used for utensils which may come in contact with foodstuffs.

Post-war Hospital Policy.—Replying to Captain Elliston's question in the House of Commons on Dec 2, Miss Horsbrugh gave the following terms of reference for the survey of London hospitals:

To survey the hospitals (other than mental hospitals and mental deficiency institutions) in London and the surrounding area, and having regard to the information thus obtained, and to the general principles of post-war hospital policy laid down by the Minister of Health in the House of Commons on Oct 9, to advise the Minister what area would appropriately be served by a hospital system centred on London, and what modifications or extensions of the existing hospital facilities would be necessary or desirable to give effect to that policy.

Dr A M H Gray and Dr A Topping are to make the survey and have already started on the preliminary work.

as the physical gallantry with which he met his death), his gift of handling the statistics which in this subject are none too adequate, his industry and his astounding facility of quotation are here exemplified Linked, not for the first time, with the solid abilities of the collaborator who survives him, they add one more to the series of reports which, like those of CHADWICK in the field of poor law and public health a century ago, compel social reform

NEW DRUGS IN PROTOZOAL INFECTIONS

IN 1935 some continental workers recorded that the drug Synthalin (decamethylene-guanidine dihydrochloride) exerted a slight therapeutic action on certain pathogenic trypanosomes in mice They ascribed this action to hypoglycæmia produced by the drug, an adequate supply of sugar being essential to the metabolism of trypanosomes, and not to a direct action of the compound on the parasites WARRINGTON YORKE and his collaborators thought that a degree of hypoglycæmia sufficient to affect the trypanosomal infections would be incompatible with the life of the host, and decided to investigate the subject further They found that, in vitro, synthalin exerted a direct and powerful trypanocidal action, a dilution of only 1 in 100 million destroying all the trypanosomes in a suspension of nutrient medium within 24 hours at 37° C They further found that the degree of hypoglycæmia produced in the normal animal by synthalin in therapeutic dosage is not pronounced The discovery that synthalin has a direct lethal action on certain trypanosomes opened up a wide field of biological and chemical investigation into the chemotherapeutic value of drugs of this and allied series in protozoal infections of man and of animals This inquiry was followed by the preparation and trial of many compounds, of which three, produced by EWINS of May and Baker Ltd, have been shown by YORKE and his co-workers to possess considerable therapeutic promise These are all diamidine compounds and are diamidinostilbene, diamidinodiphenoxypentane and diamidinodiphenoxypropane Cases of human sleeping sickness, of human visceral leishmaniasis and of babesiasis in domesticated animals have now been successfully treated with these compounds, and information is being accumulated that not only are these drugs therapeutically active in such conditions but that in some of them they are superior to any remedy hitherto employed This is more particularly the case in the Mediterranean and Sudan forms of visceral leishmaniasis, or kala azar, conditions with a very high mortality which are notoriously resistant to the antimony treatments normally effective in the Indian form of the disease

Some figures collected by STEPHENSON,[1] showing the results of antimony treatment of cases of Sudan leishmaniasis, with others collected by KIRK and SATI,[2] showing those of treatment with the diamidines, illustrate this point STEPHENSON saw 73 cases of Sudan leishmaniasis between the end of 1937 and the middle of 1939 Of these, 19 were admitted moribund and died before treatment could be begun Of the remaining 54 cases, 25 died in hospital and 22 were discharged as presumably cured, but 11 of these subsequently died Another 7 left hospital before completion of treatment and 6 of these later d The standard treatment was a course of 4 8 g Neost bosan, followed by a full course of tartar emetic, in some cases by further courses of these drugs or Anthiomaline The total result was that of 54 treated only 12 were alive in January, 1940 and SATI treated 49 cases of Sudan leishmaniasis with the diamidines, of whom 8 died Of these 8, 5 were moribund on admission, and 1, when progressing well broke out of hospital on a debauch and died within 48 hours Of the 43 cases which completed treatment 41 (95%) were provisionally regarded as cured These results compare most favourably with those obtained with the antimonials Cases treated by other workers in Palestine and elsewhere, both of the Indian and of the Mediterranean forms of kala azar show that the diamidines may effect a cure where antimony has previously been given and proved ineffective In Africa these drugs are being tested on cases of human trypanosomiasis and have been found rapidly to produce sterilisation of the peripheral blood, early cases, as a result, are cured by them So far there is inadequate information as to their effect on late cases with involvement of the central nervous system In the veterinary field the diamidines have shown much promise in the treatment of the various forms of babesiasis, a condition responsible for great economic loss among dogs and domestic stock The diamidines may be given to man in doses ranging from 0 5 to 2 mg per kg body-weight, either intravenously or intramuscularly Owing to their greater solubility, diamidinodiphenoxypropane and diamidinodiphenoxypentane are more suitable for intramuscular injection than is the less soluble diamidinostilbene The drugs may be given daily or on alternate days until 30, or even 60 or 90, injections have been administered No serious accidents have so far been recorded, although certain immediate effects lasting about half an hour occur owing to a dramatic fall in blood-pressure These are more pronounced when the intravenous route is employed, and vary from headache and dizziness with a rapid pulse, sweating and retching with occasional vomiting, to alarming symptoms in a small number of cases, where there may be syncopal attacks with temporary unconsciousness These symptoms are all transient and last but a short time, and no permanent after effects have been observed

THERAPEUTIC RESEARCH LIMITED

FREEDOM and opportunity, as SIR HENRY DALE reminded the Royal Society on Monday, provide the conditions for the highest type of research The quality of research is in fact determined by the character of those engaged in it and not by organisation or by the source of endowment Stated thus the proposition sounds self-evident Yet there is no denying the justice of the reproach made by the promoters of the new Therapeutic Research Corporation[1] that there has existed in the past a diffidence on the part of some academic research workers in this country to ally themselves wholeheartedly with the researches of industrial firms, or the rightness of the corporation's aim to establish closer liaison between industry and the research laboratories of the universities It is only a couple of months ago that we remarked in no doubt however that urine does pass into the tissues at the same time, since Kidd[1] showed that the fluid drained from the infiltrated tissues contained urea Wesson[2] successfully reproduced the clinical mode of spread of the condition experimentally by injecting coloured fluid through the urethra into the superficial perineal pouch in cadavers, and more recently Finestone,[3] in an attempt to confirm the hydrostatic theory, has carried out a series of rather similar experiments in which the spread of the injected solution (sodium iodide) was checked by serial radiograms as well as by dissection He was able to reproduce the clinical spread of extravasation only in the superficial perineal pouch and over the scrotum, the injection failing to pass up over the anterior abdominal wall or to involve the penis He suggests that this failure was due to lack of tone in the scrotum of the cadaver and to the absence of the inflammatory element In several instances the bulb of the urethra was accidentally pierced by the needle and the vascular tree injected The ease with which this occurred suggested that the importance of the vascular arrangement in this region has not been sufficiently considered in previous conceptions of the pathology of urinary extravasation Whether inflammatory or not, the disease process in its spread from the urethra must involve the corpus spongiosum with resulting thrombophlebitis This would account for the severity of the general symptoms, which are particularly serious in those patients who continue to pass water naturally, since the contraction of the bulbo cavernosus with each act of voiding helps to spread the inflammation This affords a sound argument for the diversion of the urinary stream, particularly in such cases In summarising, Finestone tries to correlate the evidence in favour of the two theories of urinary extravasation, but does not make it clear to which view he adheres himself His experiments confirm rather than exclude the importance of the infective element

DEVELOPMENT OF MITRAL STENOSIS

It has apparently been accepted without question that mitral deformity takes place slowly Had there not been much truth in the tradition it would have been questioned long ere this, but Glazebrook and Scott Thomson[4] of Edinburgh have questioned it now They report 5 cases of rheumatic fever, in 3 of which physical signs of mitral stenosis appeared within sixty days of the onset of the illness, while in the remaining 2 physical signs of aortic incompetence appeared within twenty days and disappeared after persisting for two months and seven months respectively This last observation is scarcely unexpected, but the evidence in favour of their first observation is by no means complete None of their 3 patients gave any history of previous rheumatic infection but one was aged 16 and two 15 , the mere fact that signs of mitral stenosis developed, or were detected, during the illness reported suggests strongly that there had been a previous attack, especially in view of the statement that typical radiological signs of mitral stenosis were observed by the fourth and ninth weeks of the illness The authors of the paper argue that because the subcutaneous rheumatic nodule goes through the stages of inflammation and repair with scarring in the space of a few weeks the same time interval probably applies to a similar lesion on a heart valve , but conditions in a heart valve differ considerably from those in the subcutaneous tissues It is well known that during the febrile stage of rheumatic fever a soft presystolic murmur is occasionally heard at the apex, presumably from dilatation of the mitral ring, the consequent tautness of the chordæ tendineæ producing a relative stenosis of the mitral valve, but this murmur nearly always disappears as the acute stage of the illness subsides, and presumably the presystolic murmur detected by the Edinburgh observers was not of this type That the valvular changes in rheumatic fever may occasionally result in stenosis within a comparatively short time is undoubtedly true , but Linnell and Thomson[5] put the time limit at six months, which probably represents the consensus of clinical opinion on the subject The Edinburgh findings are interesting, but until more evidence is available most clinicians will continue to work on the assumption that the development of a characteristic apical rumbling diastolic murmur during an attack of rheumatic fever points to a previous attack

THE LITTLE MORE

Lord Woolton is justly proud that today our food is more evenly distributed than ever before But though everyone is getting an adequate ration there is not much margin, and fads or dislikes may upset the balance of a finely adjusted diet Many of us have to manage without some of the semi essential luxuries to which we were accustomed, and especially among children an anxious watch is being kept for signs of deficiency diseases In his presidential address to the Society of Medical Officers of Health on Nov 21, Sir Alexander Macgregor told how a survey of the records of over 20,000 children under two years of age visited by the Glasgow health visitors during the first three months of 1939 and 1941 showed that under war-time conditions the incidence of rickets for the city as a whole had fallen, but that there was a fractional increase of mild rickets in some of the poorer localities At Great Ormond Street Dr Paterson and Dr Daynes[6] have reported 8 cases of scurvy among some 6500 patients treated up to the beginning of October this year as against 2 cases among 10,000 patients last year These are perhaps examples of vigilance rather than disease but they show that the Government's proposed free distribution of fruit juice and cod-liver oil to infants is a wise precaution Though our health is so good nutritionists are still prepared to take a benevolent interest in us The L C C and other authorities have received supplies of vitamins from America to carry out controlled experiments on their school-children But in war-time the exact goal of research must depend on the data we can obtain, and it is better to leave our destination vague until we know something of the land we are exploring and the condition of the roads on which we will travel

TREATMENT OF THE MENOPAUSE

The increasing popularity of stilbœstrol in the alleviation of menopausal symptoms has perhaps tended to an enthusiastic misapplication of this drug While most writers speak favourably of their results from this therapy, there are a few voices raised in protest and condemnation Stilbœstrol is so cheap and simple to take, and its results in many cases are so dramatic, that it is only natural for practitioners to prescribe this drug to any woman whose symptoms of whatever nature are reasonably referable to her climacteric There are, however, certain indications and contra-indications that should be more fully defined and more widely appreciated The use of stilbœstrol is primarily therapy by substitution, the deficient hormone being, in the case of the menopausal patient, the naturally occurring œstrin If we are to prescribe stilbœstrol reasonably and effectively it behoves us to define which, if any, of her symptoms are due to this œstrin deficiency The symptoms of the menopause may be, broadly speaking, divided up into groups amenorrhœa, vasomotor or circulatory symptoms (such as hot flushes, tachycardia, palpitation), dyspnœa, vertigo, cold hands and feet, numbness and tingling , nervous mani-

ECONOMISE NOW

As the inexorable economic war gains momentum, it is not surprising that produce other than food is coming more and more under the surveillance of Government departments. The man in the street is well aware of the shortage of supplies in many pharmaceutical requirements such as dusting powders, ointments and liquid paraffin. The physician too is beginning to feel that the war is cramping his style as a prescriber, but restriction of supply has served to show how difficult it is to abandon or even modify the prescribing habits of a lifetime; in fact, many recipes have become reflexes. Nevertheless, if we are to avoid the nightmare of actual rationing of drugs, we must wake up to the fact that we must economise now. Happily, when we set out to produce a particular therapeutic action there are often several ways of achieving the desired result; and when we have to choose a preparation of a drug, a great deal of latitude is permissible without significantly altering the pharmacological action. Thus there is plenty of scope for economy in prescribing; and the matter rarely involves sacrifice by anybody, though it needs forethought by the doctor. Just now the common drugs which must be used sparingly are aspirin and phenacetin, alcohol, glycerin, glucose, mercury and liquid paraffin, and unless the non-essential uses of these are curtailed those whose health really depends on them will have to go short. Even where one of them is certainly needed we must avoid ordering 8 oz. when 6 oz. will do, and the direction on the aspirin should read "Take one, and repeat if necessary," not "Take two." Before prescribing any drug, the practitioner might well ask himself two questions. First, is the substance chemically similar to any foodstuff or material which is now rationed? And secondly, does the drug come from abroad? Liniments are half-cousins to the salad dressings of happier days; ointments should be regarded with the respect we pay to the butter ration; and the recollection that glycerin is an alcohol should inspire that conservatism which evokes from the canny host an agonised "say when!" It is often forgotten that malt is primarily an emulsifying agent, and we are apt to credit it with almost mystical nutritional qualities which it certainly does not possess. War babies will be found most accommodating in swallowing cod-liver oil neat instead of malt and oil; and the substitution of vitaminised (arachis) oil should always be considered when prescribing vitamin D for children. The conservation of drugs coming from abroad presents a different problem, but experience suggests that it should not be insoluble. No one will doubt our desire to assist the Government in its economy campaign, and when the doctor errs it is usually because there is nothing to remind him of the need for caution. These are conditions which lend themselves to the use of propaganda. We are no less susceptible than the lay public to suggestion and reiteration. Eye-witness accounts of the hardships our merchant seamen undergo in order to bring essential supplies to this country are occasionally broadcast by the B.B.C. In addition to their dramatic value, these vivid descriptions of superb acts of heroism on oil tankers make every one of us think twice before using petrol unnecessarily. What is true of fuel is also true of many drugs. How can the fact be brought home to the busy practitioner? Thumbnail pictures by a Bernard Partridge or a Matania providing graphic records of these sagas of the seas might be stuck on bottles and containers used for many of the drugs in classes B and C. The greater the variety of pictorial labels the more sustained would be the interest of both doctor and patient. Furthermore the scheme could easily be extended to the use of labels which would indicate the country's approval of the physicians' choice of drugs. These pictorial reminders would undoubtedly stimulate the interest of the profession in the Therapeutic Requirements Committee's classification of drugs—an interest which will otherwise be difficult to arouse. The method is unconventional, but some sacrifice of the conventions is unavoidable if we are to cope successfully with a problem which is demanding the immediate attention of every registered medical practitioner.

QUESTIONABLE LIPOIDOSES

The publication of a work on the lipoidoses by Thannhauser (reviewed on p. 700) will raise recent controversies anew. Within the last few years Tay Sachs's disease and chondrolipodystrophy (gargoylism) have been added to the list of lipoidoses, yet Thannhauser has excluded both from his monograph. Either he does not regard these conditions as lipoid disorders, or else he considers their status to be still undecided. A discussion, by one who has contributed so much in this field of medical research, of the relationship of these two diseases to the lipoidoses of known causation would have been extremely welcome; for in the better-known lipoid disorders the nature of the biochemical disturbance has been elucidated and the character of the excessive lipoid demonstrated. Xanthomatosis, embracing many clinical types including the Schüller-Christian syndrome, is a cholesterosis; Gaucher's disease, a cerebrosidosis in which there is an accumulation of kerosin; and Niemann Pick's disease, a sphingo-myelinosis. Thannhauser emphasises the modern conception that the fundamental disturbance in the lipoidoses is an imbalance of intracellular lipoidases in the reticulo-endothelial system. In Tay-Sachs's disease and chondrolipodystrophy (gargoylism) the nature of the lipoid error is unknown. The rarity of these conditions, and the difficulty of obtaining post mortem material which has been suitably fixed for biochemical analysis and lipoid staining, are the principal causes of the failure to elucidate the precise nature of the metabolic disturbance in them; but it would seem unjustifiable to exclude these diseases from the category of lipoid disorders on this account, since they have many clinical and pathological features in common with the other lipoid diseases. Moreover, foam cells, the most characteristic feature of the lipoidoses, were demonstrated by Bielschowsky in the spleen in a case of Tay-Sachs's disease recorded by Brouwer[1], and widespread infiltration of the tissues with a heavy deposit of a lipoid substance was observed by Kressler and Aegerter[2] in a typical case of chondrolipodystrophy. Only further pathological and biochemical investigation can settle this vexed question to the satisfaction of everyone, and the fullest use should be made of every opportunity for doing so.

EXTRAVASATION OF URINE

The pathogenesis and mechanism of urinary extravasation have excited much comment in their time. Earlier observers believed that the urethra dilated behind an obstruction—nearly always a stricture—and gradually became attenuated until it suddenly gave way, usually while the patient was straining at micturition. This concept of the process was suggested by the frequent history of long standing obstruction followed by a feeling of "something giving way" and temporary relief; however, besides being open to other objections, it failed to explain the cases without organic obstruction where the patient continues to pass urine naturally. These are commoner than is generally imagined and probably constitute about 15% of all cases. The purely hydrostatic theory, although not completely discarded, has been largely superseded by the view that urinary extravasation is more of the nature of a severe cellulitis spreading from the urethra, associated in many instances with the presence of gas-forming anaerobic organisms. There is no doubt however that urine does pass into the tissues at the same time, since Kidd[1] showed that the fluid drained from the infiltrated tissues contained urea Wesson[2] successfully reproduced the clinical mode of spread of the condition experimentally by injecting coloured fluid through the urethra into the superficial perineal pouch in cadavers, and more recently Finestone,[3] in an attempt to confirm the hydrostatic theory, has carried out a series of rather similar experiments in which the spread of the injected solution (sodium iodide) was checked by serial radiograms as well as by dissection He was able to reproduce the clinical spread of extravasation only in the superficial perineal pouch and over the scrotum, the injection failing to pass up over the anterior abdominal wall or to involve the penis He suggests that this failure was due to lack of tone in the scrotum of the cadaver and to the absence of the inflammatory element In several instances the bulb of the urethra was accidentally pierced by the needle and the vascular tree injected The ease with which this occurred suggested that the importance of the vascular arrangement in this region has not been sufficiently considered in previous conceptions of the pathology of urinary extravasation Whether inflammatory or not, the disease process in its spread from the urethra must involve the corpus spongiosum with resulting thrombophlebitis This would account for the severity of the general symptoms, which are particularly serious in those patients who continue to pass water naturally, since the contraction of the bulbo-cavernosus with each act of voiding helps to spread the inflammation This affords a sound argument for the diversion of the urinary stream, particularly in such cases In summarising Finestone tries to correlate the evidence in favour of the two theories of urinary extravasation, but does not make it clear to which view he adheres himself His experiments confirm rather than exclude the importance of the infective element

BUILDERS MUST PLAN

"From the siting of a factory to the provision of a children's playground we are concerned with the right use of the land, and that is Planning"

Lord BALFOUR OF BURLEIGH

SOME parts of our cities should have been built again ong ago, some will have to be built again because they re lying flat. The opportunity ahead has been clearly tated for Birmingham in a study[1] made by the Bournville Village Trust of conditions of living and working here. The trust decided to begin the research in 1935, he material took three years to collect, and now appears n a well-illustrated book. The city can be conveniently divided into the central wards where population density reaches 62 people per acre, the middle ring with 32 people per acre, and the outer ring with 15 people per acre, this gives an average density for the city of 20 people per acre, which compares favourably with the county of London where the average pre-war density was 54, and the density in Stepney 238. Birmingham had no charter until 1838 but attracted many skilled workers in base or precious metals and other trades. In the nineteenth century growth of industry fired those speculative builders who, careless of life and health, set up street after street of back-to-back houses, of which no less than 38,000 still remain in the central wards and in parts of the middle ring. They were originally built without internal water-supply or sink, and many still have only one standpipe in the courtyard to serve a dozen or more houses. Every house in the row is surrounded on three sides by similar houses so that through ventilation or adequate lighting cannot be attained. Later, by-laws demanded air space on at least two sides of every dwelling, and those tunnel-back houses sprang up which still occupy miles of streets in the middle ring. The building of tunnel-backs, so called because the rear of each house juts backwards in a narrowing projection leaving a dank strip of yard between itself and the tunnel-back of the next house, was a nefarious way of keeping within the law and crowding houses into a site with a density of 20 or 30 to an acre. At the end of the nineteenth century came the garden city movement, bringing the semi-detached house intended for wide frontages and low density. The speculative builders snapped up the idea without conforming to the low density plan, and built thousands of closely-packed semi-detached houses in the suburbs of Birmingham, tricked out with aimless decoration which satisfied the taste of their customers without educating it.

These, then, were the three main types of house in Birmingham when the City Council undertook an inquiry in 1913, their report appeared three months after the beginning of the last war and recorded that 50,000 houses were unfit for habitation, many of them being overcrowded as well. At the end of the war building costs had risen and speculative building no longer paid, under the Housing Acts of 1919, 1923, and 1924 the municipal authorities received help which gave them the field to themselves for almost ten years. In Birmingham, 3234 houses were built under the 1919 Act, 3433 under the 1923 Act, and (over a period of 8 years) 33,612 under the 1924 Act, the result being movement of population towards the outskirts. By 1930 building costs had fallen sufficiently for private enterprise to take a hand again, and the Housing Acts of 1930 and 1935 enabled local authorities to concentrate on slum clearance and the abatement of overcrowding. Much good work had already been done, but the slums still remained. Indeed, in the middle wards, apart from provision of a separate water-supply in many houses previously without, little change had been made since the 1913 report. The number of houses built since 1920 has been greatly in excess of the corresponding rise in population, but on the other hand the average family has been growing smaller, and thus the number of families needing houses has increased out of proportion to the rise in population. However, about 10,000 houses were condemned and about 8000 pulled down between 1930 and 1938. Meanwhile private building between 1935 and 1938 was going on at the rate of 7000 houses a year in the outskirts of the city, and at the same time the corporation was building at the rate of 2500 a year. All the municipal houses were earmarked for the occupation of families displaced from the slums. Yet despite this, progress "was hardly sufficient to ensure the abolition of the slums within any tolerable period", so in 1938 the city council launched out on a five-year programme of building at the rate of 5000 houses a year. Even this number fell short of the minimum actually required within the five years, a number estimated at 17,500 for slum clearance, 3500 to abate overcrowding and 8000–10,000 to meet normal needs.

The plan has of course been interrupted by the war, but the trust in their report consider how it should be resumed when the time comes. Householders in all three regions of the city have been questioned and factory sites, transport and rentals studied, in an attempt to bring the whole mass of conflicting interests into unity. The writers of the report conclude that individualism must be tempered to fit civilisation, the city's problems must be integrated with those of the region, those of the region with those of the country as a whole, and "these in turn must be examined against the matrix of the world problem". And they are supported by Lord Balfour's definition of planning in a foreword to the report. To acquire further building land beyond the city boundaries would increase transport difficulties, and make the countryside still less accessible. The worst difficulty of planning is in the old jewellery quarters of the central wards where many small factories are thrust in among the dwellings. There is no simple solution, as the report points out, but the best plan here seems to be to build flatted factories five or six stories high, which could rehouse existing factories in less than half the space. This would make it possible to include extra services—good working accommodation, canteens, laundries, rest rooms, first-aid posts, garages, repair shops, car parks, and cycle sheds. Similar factory centres or flatted factories could be built scattered through the city and suburbs alike, and this would enable a larger number of people to live near their work. Many of the largest factories must remain where they are because removal would be too costly and complicated. Others could be removed beyond the city boundaries to form the nucleus of satellite towns. As to rehousing workers, the report shows that preference among Birmingham residents is for the separate house with a garden, but in the central wards this would simply not be possible. There is no solution for the 130,000 people living there except transfer to modern flats, maisonettes and well-planned terraced houses, built not as competing alternatives but as part of a housing scheme. The flats, like the factories, would have communal advantages—central heating, hot water, playgrounds, creches and lifts, and wide through roads and boulevards to the city would help to ease transport difficulties for those living on the outskirts.

To carry out these improvements the Bournville trust suggest that a national planning authority should be established, that the present system of land tenure should be reformed to ensure control of land for use in the public interest, and that expansion of the present city area should be stayed by enforcing the maintenance of an agricultural green belt. They propose, too, that the life of buildings should be limited by licence so that plans for reconstruction could be eased and synchronised.

DENTAL MEDICINE AT HARVARD.—On Sept 23 the new Harvard School of Dental Medicine was opened with nine students selected from different parts of America. The school has been made possible by an endowment of $1,500,000, most of which was contributed by the Carnegie, Rockefeller and Markle foundations. Under the present plan of instruction no more than 15 students may be accepted in any one class. At the new school the combined course of dentistry and medicine will last for five years and students will receive both the M D and D M D degrees. The existing Harvard Dental School will continue its present courses for three years more until members of the present second year class are graduated.

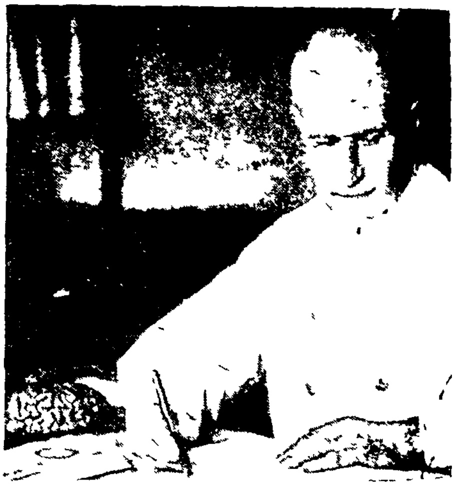
---

[1] When we Build Again. London: George Allen and Unwin. Pp 138. 8s 6d.

festations such as excitability, irritability, headache, loss of memory and power of concentration, insomnia, and depression psychosis, and a number of gastro-intestinal symptoms such as dyspepsia, flatulence, nausea, constipation and the like. One or two of these groups may dominate any given clinical picture though the patient will often produce a hotch-potch of the lot. The presence of hot flushes and other somatic sensations may well be responsible for irritability and depression and a timely treatment of the vasomotor symptoms will result in a disappearance of the emotional counterpart. But Heaver[1] points out that unless the patient's exaggerated emotional response is directly related to these vasomotor phenomena stilbœstrol may do harm rather than good. He is inclined to regard the menopause as a causative factor in precipitating an unstable patient into a state of involutional melancholia, and he states categorically that 4% of all mental diseases are to be traced to this specific source. He does not agree that the endocrine upheaval of the menopause is responsible for the psychosis, and believes that such a case is better treated by a psychiatrist. Substitution therapy by stilbœstrol in such cases may stimulate ovarian and genital activity and so increase the emotional chaos that the physician is only anxious to soothe. Heaver treated 26 established cases of menopausal psychosis with stilbœstrol. 66% of the women so treated showed withdrawal bleeding and 23% other toxic side effects such as enlargement and fullness of the breasts, areolar pigmentation, increased sexual feelings, nausea, diarrhœa and even dysmenorrhœa. From a psychological point of view 43% were unrelieved and 38% were definitely in a worse state than before treatment. The crux of the problem is whether it is justifiable to attempt to relieve vasomotor symptoms at the expense of exaggerating other aspects that contribute to the psychosexual conflict which is in part responsible for the development of the psychosis. Heaver replies that such symptomatic treatment is wholly unjustifiable. The general employment of a potent and readily obtainable drug, such as stilbœstrol, raises once more the question of more remote dangers of œstrogen therapy. No actual evidence is clinically available that this substance is in man a carcinogen, yet no one would sponsor its exhibition in say a case of established breast or uterine cancer. Moreover, the œstrogens have a remote effect on other body structures than the genital organs, certainly in small animals, where pituitary tumours have been produced. No such effect has yet been seen in human cases, but until further evidence accumulates it is as well to curb indiscriminate dosage for mild symptoms with this drug. Finally, some patients seem to acquire almost a drug addiction to stilbœstrol and once they get the taste are difficult to wean from its subtle attraction. It may well be said that all this is nebulous and fanciful, but none the less until the risks can be completely assessed the wise physician will restrict the use of stilbœstrol and other œstrogens to those cases where the indications are clear-cut.

HANS BERGER

Professor Berger died on June 7, aged 68 years. He had lived in Jena all his life, and all his work was done in the university there, where he held the chair of psychiatry and was director of the university clinic for nervous and mental diseases. Although he was a clinical psychiatrist who saw the great advances in analytical psychology modifying the approach to the psychoses which had previously been fundamentally organic (or "clinical"), he spent his life investigating mental diseases by physiological experiment. In this he was practically alone in his country, but in spite of ridicule he persistently studied the physical minutiæ of the brain in health and disease. In the late 'nineties he was measuring cerebral vascular changes, and at the turn of the century he was recording cerebral temperature with great accuracy. As these studies seemed to yield little he began in 1902 to look for electrical changes in the brain. This search was based on the tentative conclusions of Canton, von Monakow, Beck, and Horsley, but it was hampered by the limitations of electrical recording available thirty years ago. Berger employed each advance in physical knowledge as it arose believing that the change he hoped to demonstrate required more sensitive methods of recording. So his work developed with the capillary electrometer, the string galvanometer, the thermionic valve, and finally the cathode ray oscillograph.



In 1924 Berger was able to record minute electrical fluctuations from the brain of a patient who had a skull defect. He then began to study the phenomenon with Teutonic thoroughness, so that when he published his first observations five years later he had acquired a wealth of data which formed the basis of electro encephalography. In the years which followed, before his work had been recognised or had been given the seal of respectability by its confirmation in the orthodox schools of physiology, he conducted a logical series of clinical investigations backed by animal experiments. He described the characteristics of the electro encephalogram, the alpha and beta rhythms, and their modification by all forms of stimuli and experimental changes, and he also drew conclusions as to their origin and propagation. He found that detrimental factors caused slowing or abolition of the alpha waves, and he described abnormally slow waves around cerebral tumours and abscesses, in anæsthesia, and in coma due to many causes, including high intracranial pressure. He recorded abnormal waves in some forms of psychosis, especially in the dementias, and he also made important negative observations, as in the extrapyramidal diseases, in which the electro-encephalogram is normal. His initiative and perseverance were the more remarkable, not only because he was alone in this field of neurophysiology, but because electrophysiologists were concerned with single neurones and nerve-fibres, while the simultaneous change in millions of cells was unorthodox and considered hardly scientific. When his work was criticised he answered criticism by further successful experiment, and he had to modify few of his many conclusions.

As is the way with prophets Berger first received recognition abroad, and it is recorded that, when hailed as a distinguished visitor at the Paris congress of psychology in 1937, he said with feeling "In Germany I am not so famous." Even in the last years he continued to work quietly and undisturbed until his death.

Hans Berger was not an extraordinary man, nor was he an outstanding intellectual but using all his talents fully in the course he had set for himself he made rare advances in knowledge and gained an honoured place in medicine.

DR WILLIAM EVANS physician in charge of the cardiac department of the London Hospital, will deliver the third Strickland Goodall lecture, at Apothecaries Hall, in June 1942. His subject will be triple rhythm.

WE regret to announce the death, on Nov 20, in Dublin of Dr T HENRY WILSON, a former president of the Royal College of Physicians of Ireland, and King's professor of midwifery at Trinity College.

---

[1] Heaver, W L *Amer J Obstet Gynec* 1940, 40, 980

of the London and Counties Medical Protection Society The council's solicitor laid the facts before the council Asked for an explanation by the Registrar, Dr Gunn had replied that he had been very ill at the time of signing the statements He quoted the warning notice, the words of which were used in the charge

Dr J R Bulman testified that at a meeting of the Hereford Medical Board (of which he was chairman) on March 7 1941, Mr Lyward had handed to him six "certificates' relating to persons attending for medical examination These documents were signed by Dr Gunn but did not actually certify anything, being case-histories of mental cases, without verbs Witness said his suspicions were aroused because the documents used expressions which he thought no ordinary medical man would use Asked to exemplify such statements, he quoted "Lives entirely in phantasy," and "Has fetichisms" Every one of the six boys had been rejected for military service, after examination by the county psychiatrist

Mr Pereira pointed out that a school for neurotic boys had been evacuated to Ludlow, and Dr Gunn, who had taken over a practice there, was called in by the headmaster, Mr Lyward, and had been asked at the same time to attend the boys, all of whom had been sent to the school by well-known psychiatrists Later, when he was ill in bed, he had received an urgent letter asking him for a resumé of the histories for the use of the board, before which the boys had to appear at short notice He appreciated now that he should not have put his name to these histories in the way he had, though he *had* never intended to imply that the statements were of his own observation of cases

Dr Gunn testified on his own behalf, confirming his counsel's statements, and put in medical certificates as to his state of health at the time His name was not erased

* * *

The case of *Israel David Black*, registered as of 649, Leeds Road, Bradford, M B Leeds (1926), who had been summoned to appear before the council on the following charge

That being a registered medical practitioner you signed and issued the following certificates —

(1) Tel No 5276 649 Leeds Rd , Bradford
D Black, M.B , Ch B *Feb* 7, 1941
I hereby certify that Ronald Hindle residing at 30 Long St Bfd , is suffering from chill and is unable to attend School D BLACK

(2) MEDICAL CERTIFICATE
This is to certify that Ronald Hindle of 30 Long St , Bfd , attending Usher St School is suffering from chill and is not fit to attend School for a week. D BLACK

(3) Date 28/2/41 *March* 14, 1941
I hereby certify that R Hindle residing at 30 Long St Bfd , is suffering from influenzal deb and is unable to attend school
D BLACK.

whereas you had not examined the said Ronald Hindle on any of the said three days or at all, and he was in fact quite able to attend school on all the said three days, and such certificates were untrue, misleading, and improper

Dr Black was accompanied by Mr Pereira The council's solicitor said that the town clerk of Bradford had drawn the council's attention to this case, on the instructions of the city council Bradford had a custom of granting compassionate leave to children whose relatives were ill, in this case no medical certificate was required Ronald Hindle's sister was in hospital, and his mother had to look after the two grandchildren as well as her own seven and kept the boy at home to help her On Jan 7 a certificate for the compassionate ground was given by Dr Black's assistant and Ronald had been granted leave until Jan 24

Mr W Margerison, superintendent of school attendance, testified to the custom at Bradford and to the facts in this case He agreed that an officer had called at the home during the material time and found the boy out—and so presumably not ill

Mrs Selina Hindle testified that her daughter had been in hospital ten weeks with lobar pneumonia, and the baby had had fits She had sent Ronald to the doctor's for medicine for the baby and a doctor's note to continue the leave of absence already granted The assistant who had signed the first certificate was not there, and the boy had returned with document (1) in the charge She had been to the town hall and explained the circumstances On a second visit the boy had gone with her She sent the boy to the surgery again for repeat certificates during the ten weeks Dr Black was not her doctor or her family's doctor, except only the married daughter's She had been too busy to look at the certificates before sending them to the school Dr Black had sent an account last week (14*s* for the certificates), previous to that the collector had been taking 6*d* a week from her for 14 weeks She knew that the usual charge for certificates was 1s each but had made no protest at the size of the bill She emphatically denied any treatment to the boy, as Dr Black was not his, or her doctor She admitted having shown Dr Black the damp cellar of her house when he called to see the daughter's baby Ronald had been in the house at the time of the visits

Ronald Hindle confirmed his mother's account of the facts and added that during his school leave he had been distributing newspapers for his older brother

Dr Black declared that he had a large mixed general practice He had been called to see the baby on Feb 7 and had seen the baby, Mrs Hindle and Ronald He went through the house with her, saw five inches of water in the cellar and promised to report it She said they were all getting colds and that Ronald had been coughing He examined him and found bronchial catarrh He sent a certificate accordingly, with the baby's medicine At the time he had not known that Ronald had school leave on compassionate grounds He had called to visit the baby every day until Feb 17 and had seen Ronald every time Ronald was fit for school on March 18; he had attended the surgery on March 21 and asked for another certificate, he denied he had been selling papers Respondent refused a certificate He had never seen Ronald at the surgery at any other time The bill was given to the collector at the end of August

Cross-examined, he said he had destroyed—as was his custom—the visiting lists, on slips of paper from which he made up his ledger Thus there was no contemporary evidence of his attendance He destroyed this evidence in June or July, although he had heard of an inquiry into the case in May It was before he heard from the G M C

In reply to the Legal Assessor, he detailed the examination and treatment of Ronald The certificate of "influenzal debility" was an error, the boy had not previously suffered from influenza

Mr W Sergeant, Dr Black's collector, testified that accounts for Mrs Hindle and her married daughter had been handed to him about the beginning of August, and that he had called in the first week of September and seen both women, the daughter taking the accounts and paying an instalment on her own After that he had called weekly and got sums on both accounts each week Neither had ever protested about the amount He explained the system of accounting in detail

The council did not find the charges proved

ERASURE FOR ADULTERY

The case of *Eric Dickens Spackman*, registered as of 46, Shelley Road, Worthing, M R C S (1917), who had been summoned to appear before the council as a result of the divorce decree in the case of Pepper *v* Pepper (Spackman cited), dated Feb 3, 1941, he having stood in professional relationship with Mrs Pepper at all material times Respondent was represented by Mr O Hempson, and gave evidence on his own behalf, strenuously denying any adultery Strong testimonials to character and a petition signed by over 500 patients were put in, but the council directed the registrar to erase Mr Spackman's name

---

Mr T E A Stowell, F R C S , and Dr D A Coles have been re elected to the council of the Industrial Welfare Society

Sir Harold Gillies has visited America as the guest of the Academy of Ophthalmology and Otolaryngology to attend their meeting in Chicago on Oct 19 and 23, and he spoke at a special defence programme meeting held by the academy Dr R D Gillespie is visiting America at the request of the New York Academy of Medicine to deliver Salmon memorial lectures He has chosen as his subject psychoneuroses from the standpoint of war *experience* Dr Gillespie will also give addresses at Chicago, Toronto, and San Francisco

GENERAL MEDICAL COUNCIL

WINTER SESSION, NOV 25–28 1941

AT the conclusion of the President's address, reported last week (p 677), Dr Thomas Fraser was introduced by Sir Henry Brackenbury as direct representative for Scotland, Prof W J Wilson by Prof. C G Lowry as representative of Queen's University, Belfast, and Prof L G Parsons by Dr Guy Dain as representative of Birmingham University

Five names were, after deliberation in camera, restored to the Medical Register *John William Paterson Collier, William Joseph Doody, William Aloysius Kennedy, Francis Stedman Poole* and *James Pearson Thierens*

Charges against Medical Practitioners

REPORTED CONVICTIONS

The council then considered thirteen charges arising out of convictions for drunkenness, but did not erase any names save those of *John Mackay Young*, M B N Z (1923) and *John Black*, M B Belf (1921) In addition to two convictions for being drunk and disorderly Dr Black had been sentenced to one month's imprisonment with hard labour for obtaining credit by fraud

CHARGES OF IMPROPER CERTIFICATION

The case of *Alexander Cannon*, registered as of 38 Harley Street, London, W 1, M B Leeds (1924), who appeared before the council on the following charge

That being a registered medical practitioner (1) You on July 15, 1941, signed and sent to one Herbert Latreille, a district warden on the whole time paid strength of the A R P wardens establishment of Beckenham, a certificate, notification, report, or document of a similar nature dated July 15, 1941, in the following terms —

To whom it may concern This is to state that Mr Herbert Latreille is under my care and requires an immediate rest owing to the state of his nervous system and I have ordered him away for a rest from the 19th instant for a period not less than three weeks In my opinion it would be criminal to allow him to continue his work at present

ALEXR CANNON
ALEXANDER CANNON, K G C B , M D , etc

whereas you had neither seen nor examined the said Herbert Latreille at any time during the calendar year 1941, and such certificate, notification, report, or other document was misleading and improper

(2) You on October 22, 1940, signed and sent to the said Herbert Latreille a certificate dated October 22, 1940, in the following terms —

This is to certify that Herbert Latreille of Beckenham Kent is suffering from nervous exhaustion and sympathetic atonia and urgently requires 14 days rest from all duties with complete change of air away from England

ALEXR CANNON
ALEXANDER CANNON, K G C B , M D , Ph D , D P M , etc

whereas you had neither seen nor examined the said Herbert Latreille since March, 1940, and such certificate was misleading and improper And that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect

Dr Cannon conducted his own defence The council's solicitor said that Mr Latreille applied in July, 1941, to his employing local authority for sick leave in order to spend three weeks in the Isle of Man under treatment by Dr Cannon He submitted a medical certificate from a local practitioner, stating that he was suffering from boils and was recommended " three weeks' holiday (for special treatment) on the advice of his specialist " The local authority refused the sick leave but granted twelve days' ordinary annual leave Mr Latreille then sent to the chief warden the medical certificate, the subject of the first charge, which he had received the same morning, July 18 This document purported to " state," not to " certify," the matter contained in it The local authority accepted this certificate and granted Mr Latreille his sick leave Dr Cannon, when asked to explain why he had given it, wrote that he had been under the impression that a specialist could send a statement regarding a patient who was under treatment to anyone without actually seeing the person concerned He had therefore commenced the document " This is to state ", but in a later certificate which he had issued on August 8 after seeing Mr Latreille he had written " This is to certify " He had treated Mr Latreille from time to time since the beginning of 1937, the latest occasion being in December, 1940 It was arranged that he should come to the Isle of Man on July 19, but two days beforehand his wife had telephoned saying that the local authority, although he was very ill, would not let him come because he had not a medical certificate Dr Cannon had explained to Mrs Latreille that he could send the medical statement to get over the immediate difficulty, and then when he saw the patient he could issue the medical certificate This he had actually done at the end of the three weeks' treatment The facts he had stated and certified were, he wrote, true and he asked the council's forgiveness for any offence against its rules

In a further letter Dr Cannon declared that he had known Mr Latreille's condition immediately before issuing the statement of July 15, " having spoken to h wife and then himself on the phone and having mad hypnotic diagnosis through a third party that day, and which method is often more reliable than ordinary clinical findings, and as you know, the Hippocratic Oath allows me to use any means of diagnosis and treatment " In another communication, when asked to admit that he had not seen Mr Latreille at any time between Jan 1 and July 15, 1941, and between March and Oct 22, 1940, he replied that he had not seen, but had spoken to and examined the patient hypnotically on three dates during the interval in 1940 and had a telephone call and contact with him again on Oct 2 1940 , in 1941, before July 15, he had spoken to the patient and examined him hypnotically on five dates On each of the dates when he had issued a statement or a certificate he had spoken to Mr Latreille and examined him hypnotically He also sent to the registrar a copy of his book " Sleeping through Space," a chapter of which explained briefly the method he used

The council's solicitor maintained that both documents were certificates within the meaning of the council's warning notice He called Mr W J Sampson, mayor and chief warden of Beckenham, who identified the 1941 statement and testified to the circumstances in which he had received it

Mr Latreille gave evidence for the defence, confirming Dr Cannon's written explanation and saying that the documents had truly stated his condition Dr Cannon gave evidence on his own behalf and answered questions put by members of the council After the council had deliberated in camera, the President announced their finding as follows

Dr Cannon I have to announce that the facts alleged against you in the charge have been proved to the satisfaction of the council The council cannot avoid the conclusion that the certificates signed by you in your professional capacity which form the subject of the charge were certificates of the type stigmatised in para 1 of the warning notice issued by the council as untrue, misleading or improper This paragraph is presumably within your knowledge, and the attention of the profession was drawn to its special importance under all conditions by an announcement published on behalf of the council in the professional journals in April, 1941 The council regard your action in giving the certificates as a serious breach of the trust which Parliament has confided to the members of the medical profession They have listened to the description of the circumstances in which these misleading and improper certificates were given by you They do not regard that as affording any excuse for your laxity in giving them They take a grave view of carelessness in issuing certificates required by public authority , but from your statements they are prepared to believe that you sent the certificates, not from any perversity or desire to falsify, but from a mistaken view of your duties and an error of judgment Taking that into account, and believing that the warning you have received will be sufficient they have not directed the registrar to erase your name from the Medical Register

* * *

The case of *Albert Alexander Gunn*, registered as of 3 Carr Wood Road, Pownall Park, Wilmslow, Cheshire, M B Edin (1898), who had been summoned to appear before the council on the following charge

That being a registered medical practitioner you on March 5, 1941, gave certificates, notifications reports or documents of a similar nature in your professional capacity for subsequent use for administrative purposes under the National Service Acts, 1939 to 1941 in the cases of John D Collings Philip Connell Peter H Goddard, David Hobbs, D[illegible]id H C Mason and Roger Wakefield who were inmates of an institution maintained by an unqualified person one G H Lyward You had not seen or examined the persons for whom you gave the said certificates or other documents either on March 5, 1941, or at all, and the said certificates or other documents were accordingly misleading and improper

Dr Gunn was represented by Mr A A Pereira, instructed by Messrs Le Brasseur and Oakley, on behalf ndition They have practised these virtues for 20 r 30 years and the sentiment is wearing thin

* * *

Your peripatetic's note on stillbirths (disposals of) mphasises what scope for ingenuity lies in this direction among midder-boys in the East End a convenient method of disposing of the body is (or was) to wrap it up n a neat parcel and take a taxi to a point near to the ospital This was to establish an alibi The parcel ould then either be taken out and handed over to the ost-mortem department, or, better, left behind for the axi-driver to discover later and explain away to his wife One has heard it said that float-fishing in the Seine used o be ruined by the fact that during an average day's angling the catch included rather more fœtuses than fish, but this may be an exaggeration A method which may appeal to the maliciously minded is to choose a railway terminus against which one bears a grudge, hand in the parcel containing fœtus to the left-luggage office, and omit to call for it In the country the problem is less pressing than in the town In my experience there is nothing to beat a rabbit hole I remember once disposing in this way of the products of a miscarriage—no it wasn t a criminal abortion—and I confess to having felt certain qualms when I observed a great mongrel that I owned at the time, who was always hungry and dusty in the sunshine, eyeing the hole later Hens, by the way, seem very grateful for placentæ in these hard times

* * *

Why is it that so many medical men feel obliged to adopt the tone of a muscular curate when writing for the ordinary public on sex ? I am told by Dr John Drew, in his Pelican "Man Microbe and Malady" that the "sex instinct is one of the strongest, and can be one of the most ennobling, of human instincts ' In almost the same words a well-meaning clerical schoolmaster closed an unsought (and unnecessary) interview given to me in adolescence Despite the undoubted truth of the statement, the effect of such a bromide can only be either soporific or irritating, according to the mood of the reader Other phrases of Dr Drew's such as "clean and upright lives," and his description of congenital syphilis as "the atonement made by the innocent child for the sin of the parent" have likewise a clerical rather than medical ring Aldous Huxley once said that the research worker was the modern equivalent of the medieval monk, and on the whole this is probably a flattering comparison There is, however, little in common between the curate of today and the medieval churchman, and it would be a pleasant change if doctors writing on sex paid some attention to a precedent laid down by the most famous of medical monks, Rabelais

In my experience the majority of scientists outside the laboratory are a confirmed set of old women, but most people tend to think of them as cold and inhuman In the laboratory their assessment of values probably is logical rather than human Dr Drew, despite his fondness for the "human touch," is not altogether free from this The common cold for instance, is not for him just an infernal nuisance to millions of individuals but is "responsible for an enormous loss of individual and national efficiency, and for severe industrial dislocation and economic loss" Again the ravages of malaria are "estimated at 2 000,000 people annually, an annual economic loss to the British Empire alone of from fifty to sixty million pounds" Human loss cannot be assessed in terms of pounds, shillings and pence, and such estimates may be the first stage of an insidious process Its culmination finds expression in such a phrase as I heard spoken on a bus by a Homburg-hatted person after one of the spring blitzes—"It is terrible, terrible ! Think of the millions of pounds worth of damage" Something is very wrong when property and pelf are considered more important than people I do not suggest that Dr Drew thinks this, but the tendency is one that doctors should guard against

---

BRITISH ORTHOPÆDIC ASSOCIATION —The annual general meeting of this society will take place at Oxford on Jan 2 and 3 The scientific sessions will be held in the department of human anatomy at 9 30 A.M. on both days Prof T P McMurray will give his presidential address, on conservatism in orthopædic surgery, and Prof Philip Wilson, of New York, will read a paper on arthroplasty

Parliament

ON THE FLOOR OF THE HOUSE

MEDICUS M.P

THE House of Commons is now discussing a general mobilisation of the nation s man-power and woman-power which, if we were a quick thinking people, we should have done before war was declared in 1939 But we are not quick thinking or quick acting We are slow, our social organisation is heavy with a great weight of inertia

How "sure" are we in our debates, and because of this sureness of our position how tolerant The whole House spent a day debating an anti-war amendment to the address proposed by Mr Maxton s party of three And two days before that it had listened to Dr Salter opposing the war on the ground that it was a betrayal of Christ Dr Salter was seriously ill some time ago and began his speech by saying that this was "probably almost the last occasion on which I shall have the opportunity of addressing this House," but rose to oppose the present war and everything connected with it Dr Salter estimated that one in twenty of the population was against the war, he also quoted the Cardinal Archbishop of Ireland's demand for a negotiated peace and ended, "Will not somebody, for the love of God, for the sake of Christ, demand sanity and peace ? Must the war continue by its own inherent momentum until the final crash ends in prolonged anarchy and social confusion ?" But the member who followed him, while paying tribute to Dr Salter's sincerity—the sincerity of the Christian martyrs—went on blandly to discuss the Government's lack of a "wages policy" Sir George Schuster brought the debate to a high level in a carefully reasoned appeal linked with constructive proposals to make "equality of sacrifice" and "equality of service" business realities The present mongrel system of profit-making and service-giving was injuring the war effort—over the door of every business there should be a notice saying, "This business for the duration of the war is being run on account of the Government" Many debates, perhaps, on the Address are ragged and inconsequential because anything can be raised and everything, practically speaking, is in order Sir Roger Keys spoke soon after Sir George Schuster about the termination of his appointment in charge of the Commandos, while the next speaker talked about our relations with the United States and the need of a great British export trade after the war Colonel Wedgwood spoke of the Zionist offer to provide Jewish troops And so the debate went on—not a debate in any narrow sense, but a firing of argumentative broadsides at the Government Mr Greenwood, who tidied up the discussion in his reply for the Government could not of course do more than say that the matters raised would receive attention, and promise that the Government would give facilities for a debate on any aspect of the Home Front it was desired by the House to discuss

* * *

The 18B debate was a debate over a clearly limited field and was in the nature of a critical attack on the Hon. Herbert Morrison, the home secretary The amendment expressed the grave concern of the House "at the abolition of any judicial safeguard for the liberty of the subject against the arbitrary acts of the Executive" Sir Irving Albery, the mover of the amendment was backed by a large number of signatures The uneasiness felt in the House was expressed also by Commander Southby the member for Epsom, and to some extent by Mr Pethick-Lawrence and many others Mr. Morrison's case was that most of the detainees were either of enemy origin or members of the British Union of Fascists, that a large number of cases which had appealed to the advisory committee had been released, and that the number of detainees other than those mentioned was small Mr Morrison's method of defence in the past has been to attack In this debate he parried attack with gentle riposte and the House approved his defence of 18B without a division

* * *

Despite Government successes however a clear indication is emerging of the formation of opposition opinion.

In England Now

A Running Commentary by Peripatetic Correspondents

THE officer with the long gloomy face settled down in his corner and regarded me with the perseverance of one who has a story to tell. No wedding guest, I was yet sufficiently susceptible to the power of the human eye to give in, and soon the preliminaries were over and the man was retailing information likely to be of service to the enemy. I hasten to pass it on, an example of careless talk. It's a long run from the West Country to London, and I daresay we hadn't got much beyond Exeter before I knew he was attached to a blood depot —a doctor, of course, one of the pessimistic kind. It seems they are bothered by vampires. “ They get in at night you know,” he said, his voice was mournful and sincere. “ Bats and so on, you know how it is with vampires.” I said I knew my Bram Stoker as well as the next woman. “ Just so,” he answered sadly, “ we have been warned. Vampires in these days should be child's play. The whole thing has been thoroughly worked out: symptoms of infestation, course of illness, autopsy findings, treatment, methods of defestation, all the rest of it. Plenty of well-authenticated case-histories, nice statistics. Child's play.” He ruminated. “ We haven't had any bad epidemics in England, either, up to now. They're endemic in Styria, of course, or what used to be Styria,” he appended with the caution of a generation which has never had a chance to roll up the map of Europe. “ But we've been exceptionally lucky over here. Vampires and trichiniasis run about parallel.” I complimented him on our gratifying immunity. “ They're on the increase though,” he answered darkly. “ Bound to be. You've got to remember that everyone dying of vampiric anæmia (it's ordinary microcytic anæmia, of course, but the term's convenient. Israels suggested it) everyone dying of it becomes a vampire too. So they're naturally very much on the increase.” “ But surely you could get rid of them,” I demurred, and I muttered something about wild garlic and stakes, which reminded me so keenly of a pre-war luncheon that my attention wandered to my stomach for a time. When I came back into circulation he had digressed into a short lecture on vampire therapy.

“ much simpler ways nowadays,” he was saying, “ though I won't deny the old measures were pretty effective. However, it meant a lot of field work, and the apparatus cost a bit. Then locating the tombs always took some time; in fact in a badly infested neighbourhood you really needed two or three first-class vampire teams in the public health service constantly on the go, and of course the local authorities made trouble about the expense. Short-sighted,” he ended bitterly, and brooded for a while. But presently he brightened up to say that nowadays they were getting encouraging results with sulphathiazole. “ Really ? ” I asked. “ How do you apply it ? ” “ Oh to the vampire, you know, directly to the vampire,” he answered briskly. “ Not to the patient ? ” I ventured. He shook his head. “ Contra-indicated,” he said, “ because of the anæmia. No, we sprinkle it—or better still insufflate it—directly on to the vampire.” A cloud crossed his already overcast face. “ Of course you first have to catch your vampire,” he conceded, and went on dejectedly, “ Hair brushes and things like that are no good. Nor are nets over the windows or bird-lime, we've tried them all. They dematerialise, you know, vampires do.” I admitted that this property of vampires had escaped my memory. “ Oh yes,” he said, “ they dematerialise. Makes it very awkward. Come in like a bat and go out like a candle.” I said it reminded me of the month of March. “ We've even tried fitting the windows with Berkefeld filters,” he replied, unheeding, “ —no good at all.” I asked how it had begun. At first, he said, it hadn't been too bad, there had only been one vampire to start with, a reasonably considerate creature who attacked the stored blood by applying itself to a glass tube and imbibing as through a straw. “ Quite clean and orderly. Probably a doctor in his time, or anyhow a lab man.” But later the founder had brought in a friend and soon the depot had become a club for all the undead in the region, many of whom it seemed were bats of a different colour.

“ I can't give you details,” he said, belatedly cor “ but the truth is those gatherings simply became orgies. There's no other word. They took to knocking the top off the bottles.” His face wore the pained expression a man who is accountable for stores. “ They even took to plasma: simply lapped it up. And—you won't let this go any further, of course, because I've no proof and one likes to be fair—but it's my belief they're using the dried plasma like ‘ snow ’—sniffing it.” His long shocked face peered into mine, and my round shocked face peered back. Any of his colleagues from the depot would have given us a transfusion on sight. “ Things are getting worse, too,” he said, sinking his voice. “ I simply can't tell you what it was like on Walpurgis night. All the riff-raff in, and bottles going off like machine guns. You couldn't go in there—they'd have made a dead set at your external jugular.” I said imagination fairly boggled, and he agreed it did. “ And there's New Year's night coming on,” he pointed out. “ Some of them are bound to be Scots.” We thought about it silently. Bottled Scots bats. Bats wha hae Bill Wallace bled. It was likely to be quite a night. “ Then there's the medicolegal side,” he remarked abruptly. “ If they were attacking patients it would be different, but as it is we don't quite know where we stand. Are they really a medical problem at *all*, or are they breaking and entering, and should we charge them as burglars ? It's a nice point.” It was, and I was relieved when the attendant put his head in and summoned me to lunch; after all he must solve his own medicolegal problems and bottle up his own bats. Life is like that. But he sent me out shuddering all the same.

“ I sometimes wonder,” he said, leaning over impressively, “ whether there are fifth columnists among *them*.” My, *that makes you think*.

* * *

On y revient toujours, the subject of examinations and the inferences that may be drawn from results, with inevitable criticisms of the curriculum and the rationale of medical education. Evidence too should be forthcoming of the influence of war-time conditions, and possible contributions supplied to post-bellum reconstruction. We have from time to time received stout assurances from some enthusiasts who, so far from just conceding that they are making the best of a bad job, actually maintain that they are better off than ever and would prefer the perpetuation of present-day dispersal and other arrangements when we return to security and peace. Doubtless there is always a tendency to see what you expect to see. There may in some cases have been exceptional opportunities for instruction, but judging by the general standard of examinees I am persuaded that the material presented bears the hall-mark of education acquired by long application to textbooks and of deficient clinical instruction. They know all about minute difference in the varieties of leucocytes, they are very glib with the figures of biochemical problems, but they are reluctant to assess the significance of a cardiac murmur until they are provided with a radiogram and an electrocardiographic report, and a baby's belly ache is associated in their minds with an obscure “ abdominal catastrophe ” (they always spell it “ catastrophy ”). And this is precisely what I should have expected. It is the seniors on whom we should rely for the teaching of fundamentals. The *brilliant young men* of the registrar class are all very well to expound to postgraduates, but maturity and experience are indispensable for instruction of the elementary student. And with these are bound up an unanalysable quality of atmosphere, of personality (to use a question-begging term), which puts it over. It would not be surprising if the seniors are flagging. Their ranks have been depleted of the more vigorous members by the claims of the Services. Those who are left are weary, bored and disheartened. They were thrown out of their stride by the other Great War and now after the long hard effort in building up a career find themselves very much as they were twenty years ago. They had hoped for comparative leisure, for cakes and ale, and find the return to a struggle to obtain dry bread and an occasional pat of butter ill suited to their years and inclinations. They can't help asking themselves to what have they to look forward ? To sow for others to reap ? Well, they are not strangers to philanthropy, to the eleemosynary casting of bread to professional purchased and consumed by adults seeking a substitute for liquid milk. These inquiries showed that every effort was being made by the trade to restrict sales to customers purchasing the foods for infant feeding, and considerable publicity has been given to the subject in the appropriate trade paper

Central Medical War Committee

Although the full Central Medical War Committee has only met twice in the year ended Sept 30, its work has been carried on continuously by its appropriate subcommittees and by its officers in accordance with the authority which it has entrusted to them (Mr **Brown** replying to Mr T E **Groves**)

Medical History of Pension Claimants

Mr C **Stephen** asked the Minister of Pensions whether he would take steps to arrange for a medical board or medical referee in each case where there was a conflict of opinion between the panel doctor of an applicant for pension, who was acquainted with the applicant's medical history and his medical advisers, who were responsible for the rejection of the claim, to consult personally with the panel doctor and the minister's advisers, with power to recommend the grant of a pension and to avoid injustice being done to applicants for pension —Sir W **Womersley** replied It is the practice of my medical advisers to give full consideration to any opinion expressed by a man's doctor in conjunction with the evidence in the possession of the ministry Where there is a conflict of opinion and serious doubt obtains I seek the advice of an independent medical expert nominated by the president of the Royal College of Physicians or of the Royal College of Surgeons All the evidence, including the opinion expressed by the man's doctor, is placed before this independent expert whose medical opinion I always accept

No War Bonus for Panel Practitioners

Mr **Groves** asked the Minister of Health whether his attention had been called to the resolutions passed by the Doncaster and Kent panel committees, supporting the appeal for a war bonus of 4*s* to insurance practitioners , and whether he would consider this matter —Mr E **Brown** replied I have received copies of these resolutions, but I cannot see my way to grant such a bonus

No Smallpox in the Army

In reply to a question, Captain H D R **Margesson** said that no cases of smallpox have been reported in the Army since the outbreak of war

Army School of Hygiene

Mr W J **Thorne** asked the Minister how many civilian doctors had passed through an Army school of hygiene course , and how many had taken courses for treating mechanical warfare casualties —Captain **Margesson** replied I understand that the courses referred to are those given to civilian doctors on entering the Army Medical Service Some 5000 medical officers have passed through a course at the Army School of Hygiene and over 1000 through a course for the treatment of mechanical warfare casualties

Public Health

From the Annual Reports

HARROW

Dr Caryl Thomas in his annual report criticises the decision of the Ministry of Health to curtail annual reports in war-time He says " The records of the public-health activities of a stable community will show from year to year a steady progress effected , those of a rapidly growing community may present more spectacular features, but no changes in peace-time can be of the magnitude of some of the social upheavals which have taken place in so very many districts this last year " And there is much point in this argument Dr Thomas also calls attention to failure by practitioners to attend to the alteration of death-certification which became effective in 1940 as the result of the international conference The chief alteration is that formerly, when more than one cause of death appeared on the certificate, the registrar chose one for purposes of classification by an arbitrary convention In the new order the cause which the practitioner puts first is taken for the purpose of classification The practitioner should therefore take care to put first what he really believes killed his patient Up to the time of writing his 1940 report there had been no appreciable shelter ill health in Harrow but Dr Thomas fears, as we all must, that our comparative freedom from shelter disease cannot be expected to continue We shall not know until long after the war is over whether shelters were a benefit or a mistake, but it seems clear that where air attacks on a big scale are unlikely they are generally disadvantageous Dr Thomas hopes that " even should raiding have more pronounced effects in this district again, the population, having once adapted themselves to spending their nights in their own homes, will continue to feel secure there," for he thinks that the " security " of shelters is mainly the mass courage of companionship

The general death-rate of Harrow rose in 1940 from 7 1 to 9 1 crude, 11 2 corrected, and in infantile mortality from 38 5 to 50

COUNTY PALATINE OF CHESTER

This administrative county of 622,746 acres and 767,770 persons is heavily urbanised, and all but 171,250 of the population live in boroughs or urban districts There was a drop in notifications of tuberculosis in 1940 to 674 against 709 in 1939 and 802 in 1938 , but an increase in deaths from the disease to 403 against 358 and 360 in the two preceding years The mortality-rate of 0 52, though higher than those of the two previous years, is still low A table of infant feeding shows that breast-feeding is slightly commoner in the urban than in the rural districts At the end of the first month only 66% of the rural and 68% of the urban children were breast-fed and at the end of the sixth month the percentages had fallen to 48 and 47 respectively All the rates except those for the end of the third month were lower in 1940 than in any year since 1936 A further table shows that the health of children aged 2–4 years is considerably better in those who were breast-fed than in those who were not Infants are unfortunately often taken off the breast because they are sickly or feeble, so the difference in health may in part be due to this

Dr Ian Mackay, the county medical officer, comments on the increase of adulteration in foods and drugs to 9% of all samples taken, the highest on record in Cheshire The chief increase was in watered milk " Even the heavy fines inflicted on delinquents has not had the desired effect " The heaviest fine was £32 2*s* including costs against a farmer who had added 55% of water to his milk This is the highest penalty ever inflicted in Cheshire Had it been multiplied a hundredfold and taken as a precedent it might have done something to bring to an end this most frequent and pernicious form of swindling

There are 1105 persons on the blind register of Cheshire of whom only 6 are under five years of age There are 413 over seventy and 844 over fifty years of age Prevention of blindness has made good progress of recent years, but the reduction in the numbers of young blinded people is mainly due to low prevalence of diseases which threaten blindness remotely Unpreventable causes of blindness appear to be diminishing while the preventable causes are becoming less severe and are being better treated The total number does not, however, fall because, like everyone else, the blind are living longer

COLCHESTER

Dr W F Corfield reports an increase in the death-rate of Colchester from 9 2 in 1939 to 12 4 in 1940 and of the birth-rate from 14 6 to 15 6 The Registrar General's estimate of the population, on which the rates are based, was 46,400 against 52,550 in 1939, but " it is impossible to say how it compares with the actual population," and local birth-rates and death-rates for 1940 cannot be reliable But infantile mortality, which is the most sensitive index of the health of populations and is independent of their age-sex composition, more than doubled, from 28 5 to 58 5, and Dr Corfield says " It is difficult to account for this great increase , probably war conditions have a good deal to do with it " The isolation hospital admitted 82 cases of cerebrospinal fever in 1940, but there was only one death

Infectious Disease in England and Wales

WEEK ENDED NOV 22

Notifications —The following cases of infectious disease were notified during the week smallpox, 0 , scarlet fever, 1417 , whooping-cough, 1995 , diphtheria, 1082 , paratyphoid 18 , typhoid, 10 , measles (excluding

There are several oppositions—there is no destructive opposition But that a constructive opposition will emerge is probably only a question of time

FROM THE PRESS GALLERY

Women's War Work

APART from sidelights on sartorial refinements such as uniforms for munition-workers and motley for the noble lords on the cross benches, some useful points emerged from the debate on women's war work in the House of Lords on Nov 25 Lord **TRENCHARD** was especially concerned with conditions in the Auxiliary Territorial Service which he thought had never had a fair chance On its inception in 1938 it had been run by very junior Army officers and even now there was still too much masculine interference with discipline and training He was old-fashioned enough to dislike seeing a woman doing a man's work even in these hard times, and he was not sure that parents approved of the A T S working with men in small units scattered about the country He thought there was a lot to be said for retaining some older women as officers Lord **SAMUEL** spoke of the general call-up of women He thought the experience and ability of interviewers had often been to seek and that there was a lack of uniformity in the standards of the medical examinations He deplored the long hours worked by women in some factories There were still many complaints of the inadequacy of canteens and an insufficiency of day nurseries More welfare officers were needed in industry, or many evils, though recognised as evils, would still continue If women were to be conscripted good use must be made of them Lord **STRABOLGI** thought a tremendous lot depended on whether Mr Bevin or Dr Ley won the race in mobilising married women for the factories To this end the provision of day nurseries was crucial and urgent, yet the Ministry of Health was moving in a ponderous, peace-time, bureaucratic way Lord **CROFT**, who replied for the Government, declared that the War Office was not prepared to treat women as though they were tough soldiers nor as though they were a women's university in time of peace But the approved scale of accommodation for women was decidedly better than for the men They tried to keep women's units separate from the men's, but as in many other walks of life it was not always possible All the A T S units were now commanded by women and when women are trained for staff duties they would be used Till then the final responsibility must rest with the Service Lord **SWINTON** made a plea to give women the minimum of man-made drill and the maximum of training by women for the jobs they would have to do. Lord **TRENCHARD** was doubtful whether Lord Croft had given an assurance that women were to run their own services Lord Croft seemed to infer that there were not enough women trained to run their services, but were there any men trained to do the work of training women?

Uneasiness about recruitment to the A T S was also reflected in the debate on the Address in the Commons Captain J H F **McEWEN** thought the problem was feline not ovine It was useless for the Minister of Labour to go about the country bellowing like a wounded rhinoceros, threatening conscription and appealing to women's sense of adventure, for most women only wanted security Captain McEwen' was sorry the glamour recruiting poster had been withdrawn, it was the only theme which would attract many women Mr C **STEPHEN** agreed that women wanted security rather than adventure, but suggested offering them the more rational baits of social equality and equal compensation and pensions with men

Incidence of Tuberculosis

Mrs. J L **ADAMSON** asked the Minister of Health whether, in the inquiry by the M R C into the causes of the increase of tuberculosis in girls and women of 15–30 years of age, he would ascertain the nature of their occupations, and if the increase was revealed as a result of medical examination not normally undertaken in peace time Mr E **BROWN** replied I understand that the M R C, in the course of their inquiry, will consider such evidence as is available as to how far occupational circumstances have a bearing on this problem The trend of tuberculosis has been revealed by information compiled by the Registrar-General in the normal way

QUESTION TIME

National Wheatmeal Flour

Sir **ERNEST GRAHAM-LITTLE** asked the secretary to the Ministry of Food what machinery existed the dissemination and enforcement of the statutory defining national wheatmeal flour, whether he was that notwithstanding this order national wheatmeal flour 85% extraction might consist merely of white straight flour with added bran, and whether this compo accorded with the specification furnished by the M Research Council in its second memorandum, published in spring of 1941 —Major G **LLOYD GEORGE** replied N wheatmeal is made by controlled flour millers, and, in the manufacture of this product, they are bound by the statutory order defining national wheatmeal and also by the more precise instructions regarding its manufacture which were issued to secure adherence to the recommendations of the Medical Research Council The Minister has the necessary powers to secure compliance with such orders and instruction A composition consisting of white straight run flour with added bran would not accord with the specification of the M R C, nor would it be in accordance with the manufacturing instructions issued to millers

Control of Disease in Dairy Cattle

Mr M P **PRICE** asked the Minister of Agriculture what steps had been taken to set up a scheme for the regular inspection of dairy cattle by voluntary arrangements with farmers for the elimination of contagious abortion, mastitis and Johne's disease, and for the provision of serum at special rates for this purpose —Mr R S **HUDSON** replied The arrangements for a voluntary scheme for the control of certain of the major diseases of dairy cattle are in an advanced stage of preparation, but difficulties in connexion with the choice of the most suitable contagious abortion vaccine have somewhat delayed its inception I hope, however, that this difficulty will shortly be resolved

Weybridge Tuberculin Test

Major E G R **LLOYD** asked the Minister whether, in view of the experience of Scottish and English herd owners with the Weybridge tuberculin test and the lack of confidence felt in the test by the industry, he would consider discontinuing the use of the recently introduced tuberculin and reverting to the type of preparation formerly used pending further scientific investigation, and whether he would consider the advisability of arranging a conference between representatives of Scottish and English herd interests and veterinary medical associations to discuss this matter in the light of their respective experiences —Mr **HUDSON** replied The whole question of tuberculin and the tuberculin test has for some time been under investigation by the joint tuberculosis committee of the Agricultural Research Council and the M R C, and I propose to await the findings of that committee before taking any fresh step in the matter

Children of Women Workers

Mr **GORDON MACDONALD** asked the President of the Board of Education what steps he was taking to safeguard the health of school children whose mothers were employed on war work. —Mr R A **BUTLER** replied I have asked local education authorities to give particular attention to the need of providing meals for school children whose mothers are employed on war work

Mr K **LINDSAY** asked the minister whether he would give a 100% grant to local education authorities who wished to stimulate nursery provision for children under five —Mr **BUTLER** replied It has been decided that where new nursery classes are provided in public elementary school premises, especially to meet the needs of the children of women war workers, the authorities' expenditure will be eligible for 100% grant from the Ministry of Health as expenditure on war time nurseries

Out of the Mouths of Babes

Mr D L **LIPSON** asked the parliamentary secretary to the Ministry of Food if he was aware that patent baby foods were being consumed by adults seeking a substitute for milk, and as the supply of baby food was limited, would he take steps to see that it was reserved for those for whom it was intended —Major **LLOYD GEORGE** replied Patent baby foods are not controlled by the Ministry of Food, but an infant food manufacturers group has been formed after consultations between the ministry and the trade Inquiries have recently been made into the allegation that such baby foods are being enry Cohen and Sir Robert Kelly reported little value om the operation in a series of 10 cases, but in 1936 Frazier and S N Rowe recorded 8 operations on a ries of 5 patients with considerable improvement in 2 oth cases however relapsed after the first operation and equired a second, their later history is not known y own experience of myelotomy in 3 cases was ufficient to convince me that the operation has no ermanent effect on symptoms and no curative effect on he process itself

Manchester　　GEOFFREY JEFFERSON

CADMIUM POISONING

SIR,—The recent publication (*Chem Age Lond* 1941 45 259) of a precis of a report on 208 cases of acute poisoning resulting from the use of cadmium-plated food utensils is of interest after reference to 3 somewhat similar cases in the report of the Chief Medical Officer to the Ministry of Health for 1935 (p 155)

Last year there were 8 cases of acute cadmium poisoning in Walthamstow

In May, 1940, 3 adults and 5 children were found to have become acutely ill some 15 minutes after consuming "lemonade ices" prepared by freezing "lemonade" in the metal trays of a reconditioned refrigerator All were sick and 4 had diarrhœa, but recovery was generally complete within 24 hours The remains of the unconsumed "lemonade ices were not available but the method of preparation was repeated This consisted of dissolving a popular brand of lemonade crystals (consisting of citric acid and sugar) in boiling water and freezing overnight in the refrigerator Analysis showed that the trays had been plated with cadmium on copper and that there was up to 279 p p m of cadmium in solution This roughly represented gr 1/20 of cadmium per "ice" block It therefore appears that this quantity of cadmium may cause somewhat severe poisoning The refrigerator was of a well known make but had been supplied second hand by another firm It had then acquired cadmium plated copper trays not supplied originally The supplying firm was instructed to warn all its customers of the danger of making "lemonade ice" in similar trays The original manufacturers were naturally most anxious to investigate the matter but the supplying firm unfortunately proved non coöperative in regard to tracing back the persons responsible for the replating of the trays with cadmium

The quantitative toxicity of cadmium has apparently not yet been clearly established but it is sufficiently dangerous for its use to be prohibited in colouring matters for foodstuffs

I wish to acknowledge the assistance of Mr George Taylor, F I C, public analyst to the borough of Walthamstow

Walthamstow　　A T W POWELL

GRADUATION AT AN EARLIER AGE

SIR,—I would refer Dr Rogerson, who doubts my facts, to the PEP report on British Health Services (p 137) "In 1938 a student will not be permitted to register before 18 　 The course cannot be completed in less than six years at some medical schools, or less than five and a half at others, and one single failure through bad luck or sickness may make the course six months or a year longer" The B M A. recommend another year in house jobs, prolonging the course to seven years or so

This late age of graduation to some extent explains why out of 18,901 married doctors according to the 1931 census, only 5 8% were married before the age of 30 This figure does not take account of those who never marry at all, so it is on the high side Statistics show that, on the average, a wife is not more than a year younger than her husband, and as fertility in primiparæ falls rapidly after 30 it is little wonder that the doctor's nursery is almost empty

Do specialists fare better? "A young man will hardly keep himself for the first ten years that he is in specialist practice" (p 160) I looked up at random 50 honorary physicians and 50 surgeons at London hospitals in Who's Who 1940 Their average age was 52 and the average age on marriage was 32 6 About a quarter (24%) had no children at all, 42 had no male issue while only 3 had five children

With regard to an earlier start in medicine, Dr Rogerson wants to know what intelligence is "In so far as there is a common meaning to the word intelligence we may say that it corresponds to *g*" according to R Cattel, quoted with approval by Professor Spearman the greatest authority on the subject who says that *g* ceases to grow after 13 or 14 Conative factors, of course, are also important, and my contention is that enthusiasm for learning is less under a system where graduation is virtually at 26 and the chances of making a home by the age of 30 is only about one in twenty Dr Rogerson's misgivings as to whether a man at 21 can be safely given responsibility sounds strange in an age when our youth is showing such resourcefulness and leadership as indeed they always do when given the chance

Mr Bates, who seems to think two blacks make a white says we are no worse off than other professions, but it is to us that the public come for advice on size of family, and we ought to put our own house in order first The G M C have not only made biology and psychology compulsory for students but genetics as well Perhaps the student of tomorrow will say to the G M.C. "Biology tells us that the best age for parenthood is 24–32, so why may we not be encouraged to settle down by then? Psychology teaches that mental health is benefited by an emotional life appropriate to one's years a full nursery in the thirties and grandchildren to brighten one's declining years I am not satisfied with a system that gives me only one chance in twenty of a home of my own at the age of 30 or if I am a specialist only forty-eight chances in a hundred of having a son to carry on my name Surely you educationists can get together to devise a system which will give us a logical mind, a love for knowledge, and professional skill by the age of 21"

I would not however go so far as Mr Bates in hinting that only communism can remedy all this Some of our youth will always prefer a "good time" to civic responsibilities but if the authorities would act we could have an efficient system of education which would enable those who wished to do so to start at 16 graduate at 21 and become householders by 24 or 25 Care must be taken that able men are not penalised professionally for doing so Some such system is bound to come and we shall hear a great deal more on the subject in the next few years, when facts force the Government to adopt some sort of population policy

Aylesbury　　A SPENCER PATERSON

PROBLEMS IN HÆMAGGLUTINATION

SIR,—With reference to your leading article of Oct 25, I should like to stress the fact as I did previously (*Brit med J* Nov 23, 1940, p 721) that the indiscriminate use of O serum or plasma is in fact not the best procedure for emergency transfusion Individuals belonging to group O must only be considered as universal donors if whole blood is transfused When the corpuscles are excluded and only plasma is used O individuals are least suitable as universal donors because their plasma contains both anti-A and anti-B agglutinins The ideal of utilising AB serum generally for this purpose cannot be attained because of the scarcity of this group On the other hand, A plasma or serum is more suitable than O plasma or serum because it contains only *anti-B* agglutinins Group A is, at least in the southern part of England, about as common as group O, so that it would not be more difficult to collect A blood than O blood Any danger caused by agglutination of the recipient's corpuscles is then avoided if the recipient belongs to group O or A Only about 15–18% of the population (groups B and AB) would then remain in whom the possibility of agglutination of their corpuscles by A serum would arise Further, *since* anti-B agglutinins are usually weaker than anti-A agglutinins in these cases the likelihood of damage would seem to be less than that which might result from the transfusion of *O serum to A* and AB individuals Hence preference should be given to A serum (or plasma) rather than to O serum if homologous blood is not available

The method utilised by B L Della Vida and S C Dyke (*Lancet*, 1941, 1, 564) of mixing O serum with A and B serum may not always be reliable The amounts of A and B antigens detectable in serum are different. The serum of A_2 blood usually contains weaker A antigens than that of A_1 The full action of the iso-antigens present in serum is often only detectable by special rubella), 639 , pneumonia (primary or influenzal), 1100, puerperal pyrexia, 142 , cerebrospinal fever, 114 , poliomyelitis, 13 , polio-encephalitis, 0 , encephalitis lethargica, 2 , dysentery, 209 , ophthalmia neonatorum, 59 No case of cholera, plague or typhus fever was notified during the week

The number of civilian and service sick in the Infectious Hospitals of the London County Council on Nov 19 was 1321, including scarlet fever, 174 diphtheria, 286 , measles, 37 , whooping cough, 487 , enteritis, 37 , chicken pox, 37 , erysipelas, 26 , mumps, 7 , poliomyelitis, 4 dysentery, 25 , cerebrospinal fever, 12 , puerperal sepsis 16 enteric fevers 35 , malaria, 1 , other diseases (non infectious), 60 , not yet diagnosed 77

Deaths —In 126 great towns there were 1 (0) deaths from enteric fevers, 3 (0) from scarlet fever, 2 (0) from measles, 9 (2) from whooping-cough, 27 (0) from diphtheria, 35 (2) from diarrhœa and enteritis under 2 years, and 25 (5) from influenza The figures in parentheses are those for London itself

There was 1 death from an enteric fever at York Liverpool reported 7 fatal cases of diphtheria

The number of stillbirths notified during the week was 192 (corresponding to a rate of 39 per thousand total births), including 13 in London

CHILDREN IN SHELTERS

How much time should children spend in air-raid shelters ? At first glance the answer would seem to be " As little as possible," but at a conference arranged by the Save the Children Fund, and held at Friends House on Nov 29, the question was not felt to be simple Evacuation was not discussed, because all agreed that London was not the proper place for children during a war But there are children in London, and their welfare must be considered, for as Mr **Kenneth Lindsay**, M P , pointed out in his opening address they are exposed not only to bombs but to anything the war may bring along If during the winter months children are encouraged to come to the shelter in the evenings they are at least off the streets, and their parents know where they are , but of course it would be better, as most speakers agreed, if there were enough properly organised boys and girls clubs or play centres for them to attend instead

How far, then, can the shelter be made to serve the purpose of a play centre and is it desirable that it should be used in this way ? In some boroughs many parents are now sleeping at home and sending the children to the shelters to sleep , in others, where no children under 14 are allowed to sleep in the shelter without their parents, many children come to the shelter to meet their friends before going home to bed Thus the children themselves are treating their shelter as a rendezvous If there are no organised occupations for them they find their own amusements, which include card-playing for money and smoking Those between 10 and 14, who feel on the brink of complete citizenship, are naturally the most prone to these adult pursuits , but in one shelter, as soon as a counter attraction in the form of aeroplane modelling was presented, the children forsook gambling to become absorbed in it They want an occupation—one speaker said " they're like a dry sponge " —but they want the occupation to have some point to it They would rather make Christmas decorations for the shelter than raffia mats , they would rather paint a cupboard than a picture book , they like better still to be doing something which they feel is helping the troops or the war effort , and most significant of all, they do not use the term "play centre " among themselves—they speak of the " centre " or the " club " They like going to clubs and centres because they " get the chance to make things " , and they rightly regard the word " play" as an affront No-one would tell an artist to go and play in his studio or a carpenter to play at his bench

If the shelters, then, are to be used as temporary and accessory centres in areas which lack sufficient provision of the kind—and most speakers agreed that shelters should take on this extra duty—they must offer the children something cooperative and responsible in the way of occupation , work for the improvement of the shelter itself, or project work giving them an insight into a trade or social service Mr Lindsay saw the situation as another opportunity to " cash in on the war " , and his dream of a Ministry of Childhood and Youth may begin to have a material foundation in work starting now in the shelters

Letters to the Editor

ABOUT THE CHRISTMAS GIFT FINAL

Sir,—Referring to my appeal on behalf of the Christmas Gifts fund of the Royal Medical Benevolent Fund, I recently received a letter from a doctor, aged 7 He and his wife, aged 72, are both beneficiaries of the fund and their joint income is £169 They have been recipients of our Christmas gifts and their letter states –

" As Christmas approaches we think of the special gift which the Committee has so kindly sent us for several years, but would like to make a suggestion Since we came to the little farm worker's cottage we find expenses are easier than formerly It would, therefore, give us much pleasure if our Christmas gift this year was given instead to someone who has been bombed out of home "

Many of our beneficiaries have unfortunately suffered through enemy action May I, through your columns, ask those of your readers who have not yet responded to my Christmas appeal to send in their contributions as soon as possible addressed " Christmas Gifts," Royal Medical Benevolent Fund, 1, Balliol House, Manor Fields, London, S W 15

Thos Barlow,
President, R M B F

WHAT'S IN THE LOAF?

Sir,—Your leader of Nov 15 and the admirable letter from Dr Swindells (Nov 22) should spur the medical profession to the realisation of their ultimate responsibility as guardians of the public health for what you describe as the present "strategically bad" situation of the national wheatmeal loaf

Recent parliamentary answers reveal that the Ministry of Food has expended during the past year over half a million sterling on its advertisements, including those of the " national wheatmeal loaf " and that notwithstanding these costly efforts at persuasion the sale of that loaf represents only about 7% of the total consumption of bread in this country Moreover, the Parliamentary Secretary was constrained to admit that the national wheatmeal loaf now in the market is of entirely variable composition, and is impossible to obtain over wide areas of the kingdom The rise in the mortality from tuberculosis during the past two years, indicated in several recent parliamentary answers, suggests an increasing measure of malnutrition in the community, one factor of which may be the admittedly poor nutritive value of the white loaf, which throughout the country (except for one district in Wales) apparently still consists of straight-run flour (75% extraction), deprived of the germ and without any of the " fortification " promised 18 months ago by the addition of synthetic vitamin B_1 and calcium If the influence exercised by the milling industry, with its formidable occupation of key positions in the Ministry of Food, is the explanation of the otherwise inexplicable reluctance of that ministry to make provision for the highest possible extraction flour for the national war-bread, public opinion will hardly allow the obstacle of vested interests to resist indefinitely so urgent and obvious a reform This provision was made with success in the last war, and has been urged by practically unanimous scientific and medical opinion, strongly fortified by the statement, for which the ministry itself is responsible, that universal consumption of the wheatmeal loaf would result in the saving of one-fifth of shipping space I submit that the medical profession should lead the revolt

House of Commons **E Graham-Little**

SURGERY FOR SYRINGOMYELIA

Sir,—In your annotation (*Lancet*, Nov 22, p 644) you invite neurosurgeons to give their experience of the surgical treatment of syringomyelia Some have already done so , I summarised their findings in the Medical Annuals of 1933 (p 471), 1936 (p 427) and 1937 (p 421) A Juzelevskij in 1935 reported on 23 cases , he found that opening up of cavities in the cord only gave partial and temporary relief of symptoms, which in some cases recurred within a fortnight He also found that the pressure of the fluid in the cavity was the same as that of the cerebrospinal fluid in the theca, so that there was no question of relieving tension In the same year nry Cohen and Sir Robert Kelly reported little value m the operation in a series of 10 cases, but in 1936 Frazier and S N Rowe recorded 8 operations on a ries of 5 patients with considerable improvement in 2 oth cases, however relapsed after the first operation and quired a second their later history is not known own experience of myelotomy in 3 cases was fficient to convince me that the operation has no rmanent effect on symptoms and no curative effect on e process itself

Manchester GEOFFREY JEFFERSON

CADMIUM POISONING

SIR,—The recent publication (*Chem Age Lond* 1941 5, 259) of a precis of a report on 208 cases of acute oisoning resulting from the use of cadmium-plated food tensils is of interest after reference to 3 somewhat similar ases in the report of the Chief Medical Officer to the Ministry of Health for 1935 (p 155)

Last year there were 8 cases of acute cadmium poisoning in Walthamstow

In May, 1940, 3 adults and 5 children were found to have ecome acutely ill some 15 minutes after consuming "lemon ade ices" prepared by freezing "lemonade" in the metal trays of a reconditioned refrigerator All were sick and 4 had diarrhœa, but recovery was generally complete within 24 hours The remains of the unconsumed "lemonade ices *were not* available but the method of preparation was repeated This consisted of dissolving a popular brand of lemonade crystals (consisting of citric acid and sugar) in boiling water and freezing overnight in the refrigerator Analysis showed that the trays had been plated with cadmium on copper and that there was up to 279 p p m of cadmium in solution This roughly represented gr 1/20 of cadmium per "ice" block It therefore appears that this quantity of cadmium may cause somewhat severe poisoning The refrigerator was of a well known make but had been supplied second hand by another firm It had then acquired cadmium plated copper trays not supplied originally The supplying firm was instructed to warn all its customers of the danger of making "lemonade ice" in similar trays The original manufacturers were naturally most anxious to investigate the matter but the supplying firm unfortunately proved non coöperative in regard to tracing back the persons responsible for the replating of the trays with cadmium

The quantitative toxicity of cadmium has apparently not yet been clearly established but it is sufficiently dangerous for its use to be prohibited in colouring matters for foodstuffs

I wish to acknowledge the assistance of Mr George Taylor, F I C, public analyst to the borough of Walthamstow

Walthamstow A T W POWELL

GRADUATION AT AN EARLIER AGE

SIR,—I would refer Dr Rogerson, who doubts my facts, to the PEP report on British Health Services (p 137) "In 1938 a student will not be permitted to register before 18 The course cannot be completed in less than six years at some medical schools, or less than five and a half at others, and one single failure through bad luck or sickness may make the course six months or a year longer" The B M A recommend another year in house jobs, prolonging the course to seven years or so

This late age of graduation to some extent explains why out of 18,901 married doctors, according to the 1931 census, only 5 8% were married before the age of 30 This figure does not take account of those who never marry at all, so it is on the high side Statistics show that on the average, a wife is not more than a year younger than her husband, and as fertility in primiparæ falls rapidly after 30 it is little wonder that the doctor's nursery is almost empty

Do specialists fare better? "A young man will hardly keep himself for the first ten years that he is in specialist practice" (p 160) I looked up at random 50 honorary physicians and 50 surgeons at London hospitals in Who's Who 1940 Their average age was 52 and the average age on marriage was 32 6 About a quarter (24%) had no children at all, 42 had no male issue, while only 3 had five children

With regard to an earlier start in medicine, Dr Rogerson wants to know what intelligence is "In so far as there is a common meaning to the word intelligence we may say that it corresponds to *g*" according to R Cattel, quoted with approval by Professor Spearman the greatest authority on the subject who says that *g* ceases to grow after 13 or 14 Conative factors of course, are also important, and my contention is that enthusiasm for learning is less under a system where graduation is virtually at 26 and the chances of making a home by the age of 30 is only about one in twenty Dr Rogerson's misgivings as to whether a man at 21 can be safely given responsibility sounds strange in an age when our youth is showing such resourcefulness and leadership, as indeed they always do when given the chance

Mr Bates, who seems to think two blacks make a white, says we are no worse off than other professions, but it is to us that the public come for advice on size of family, and we ought to put our own house in order first The G M C have not only made biology and psychology compulsory for students but genetics as well Perhaps the student of tomorrow will say to the G M C "Biology tells us that the best age for parenthood is 24–32, so why may we not be encouraged to settle down by then? Psychology teaches that mental health is benefited by an emotional life appropriate to one's years a full nursery in the thirties and grandchildren to brighten one's declining years I am not satisfied with a system that gives me only one chance in twenty of a home of my own at the age of 30, or if I am a specialist only forty-eight chances in a hundred of having a son to carry on my name Surely you educationists can get together to devise a system which will give us a logical mind, a love for knowledge and professional skill by the age of 21"

I would not, however, go so far as Mr Bates in hinting that only communism can remedy all this Some of our youth will always prefer a "good time" to civic responsibilities, but if the authorities would act we could have an efficient system of education which would enable those who wished to do so to start at 16, graduate at 21 and become householders by 24 or 25 Care must be taken that able men are not penalised professionally for doing so Some such system is bound to come and we shall hear a great deal more on the subject in the next few years, when facts force the Government to adopt some sort of population policy

Aylesbury A SPENCER PATERSON

PROBLEMS IN HÆMAGGLUTINATION

SIR,—With reference to your leading article of Oct 25, I should like to stress the fact as I did previously (*Brit med J* Nov 23, 1940, p 721) that the indiscriminate use of O serum or plasma is in fact not the best procedure for emergency transfusion Individuals belonging to group O must only be considered as universal donors if whole blood is transfused When the corpuscles are excluded and only plasma is used, O individuals are least suitable as universal donors because their plasma contains both anti-A and anti-B agglutinins The ideal of utilising AB serum generally for this purpose cannot be attained because of the scarcity of this group On the other hand, A plasma or serum is more suitable than O plasma or serum because it contains only anti-B agglutinins Group A is, at least in the southern part of England, about as common as group O, so that it would not be more difficult to collect A blood than O blood Any danger caused by agglutination of the recipient's corpuscles is then avoided if the recipient belongs to group O or A Only about 15–18% of the population (groups B and AB) would then remain in whom the possibility of agglutination of their corpuscles by A serum would arise Further since anti-B agglutinins are usually weaker than anti-A agglutinins in these cases the likelihood of damage would seem to be less than that which might result from the transfusion of O serum to A and AB individuals Hence preference should be given to A serum (or plasma) rather than to O serum if homologous blood is not available

The method utilised by B L Della Vida and S C Dyke (*Lancet*, 1941, 1, 564) of mixing O serum with A and B serum may not always be reliable The amounts of A and B antigens detectable in serum are different The serum of A_2 blood usually contains weaker A antigens than that of A_1 The full action of the iso-antigens present in serum is often only detectable by special physico-chemical methods Thus the way suggested by E Witebsky, N C Klendshoj and P Swanson (*J Amer med Ass* 1941 **116**, 2654 see also *J infect Dis* 1940 **67**, 188, *J exp Med* 1940 **72**, 663)—namely, the addition of the purified group-specific carbohydrates to the serum—should on principle be considered an advance though it may be difficult to obtain sufficient supplies of the purified B substance

Finally it may be mentioned that all errors in grouping (including those originating from auto- or cold-agglutination) may be avoided by examining the corpuscles as well as the serum In adopting this combined method some difficulties may be encountered when very many examinations are wanted in a hurry for the transfusion services Nevertheless it is the only way to be sure of obtaining correct results and avoiding all possibility of mistake This is illustrated by the unusual case reported by H J Parish and R G Macfarlane (*Lancet*, Oct 25 1941, p 477), in which ionised calcium played an inhibiting part against antoagglutination produced in citrated blood For if serum or plasma is also examined against its own corpuscles as is always desirable, such a peculiarity would be recognised immediately

School of Pathology, Trinity College Dublin H Sachs

LOCAL APPLICATION OF SULPHONAMIDES

Sir,—One secret of success in sulphonamide therapy is to give as much of the drug as the patient can tolerate in the first few days Where the infection is a local one and accessible more use should, I feel be made of local application, for this will produce an effective concentration of the drug where it is wanted more rapidly than oral or parenteral administration and will not produce the same nausea For instance when treating a local infection of the nasal cavity a well-powdered tablet may be inserted into the nostril It is surprising too, that local application has not been more freely used in treating gonorrhœa The passage of instruments through an acutely inflamed passage' is contra-indicated, but the manufacturers might consider supplying sulphapyridine or one of the allied compounds in the form of slightly pliable rods up to 3 in long to be inserted into the urethra once the acute stage has subsided and left in position until the patient passes his urine More local application should result in a considerable saving in drugs, an important consideration where expensive remedies are employed on a large scale, as among native communities

Durban, South Africa F Gordon Cawston

GERMAN BLOOD SUBSTITUTE

Sir,—In your annotation of Nov 1 (p 533) you refer to a crystalloid solution named Tutofusin which is used as a blood substitute in Germany, but the composition of which is not mentioned in the article you cite Tutofusin has been manufactured for about eight years by J Pfrimmer and Co of Nurnberg According to the announcements of that firm it consists of "several serum salts," and has been employed both for intravenous infusion and also as a base for local anæsthetics

Cambridge G Brock

ENURESIS

Sir,—The number of letters on the treatment of enuresis seems to indicate that this condition is still difficult to cure The method which I follow—faradism to the perinæum—is almost invariably successful I saw it described first in a French textbook of surgery about 18 years ago The writer stated that it acted by stimulating the perinæal muscles and was successful in over 50% of cases I had much more success with it than that but soon came to the conclusion from watching the reactions of the patients and seeing the varying times it took to cure them that it acted by influencing the child's subconscious mind It is described in the Index of Treatment by Sir Robert Hutchison who says that being painful it is hardly to be distinguished from punishment With this I cannot agree I have heard of boys who have gone all through their public school wetting the bed every night A major operation which would cure the horrible habit would be welcomed and why should a course of faradism be regarded differently? There are certain conditions which must be fulfilled if success is to be obtained

1 The child must be of an age when it can realise bedwetting is a horrid business, and can understand that treatment although painful is in no way regarded as a pu ment but is used as the only certain method of cure

2 The parents must cooperate If the child is an one and much spoiled this sometimes presents a diffic the arguments used above usually convince them that it necessary It failed in one case whose mother said, ' little thing, he can't help it, I do it myself sometimes and does my husband '

3 The treatment must be given by someone who will kind and very firm, preferably a nurse of some standing wi experience of electrotherapeutic methods

The treatment is given before the patient goes to bed and patient, parent and nurse must understand that a inevitably as night follows day so will faradism to the perinæum follow bedwetting on the previous night A few treatments are generally sufficient but if not the strength of the current is increased until it becom decidedly unpleasant There seems no limit to the a at which this will succeed I have cured one youth of 18, but I should not care to try it on children of 3 or 4 That is to say it is suitable for the really difficult cas and it is in the hope of helping these that I write th letter

F R C S

THE DISCHARGING EAR

Sir,—No-one can accuse Mr Layton of lack of versatility or obscurantism, but it is surprising that in discussing otitis media and the discharging ear in his lecture "Medicine and Duty" he makes no mention of treatment with a quartz applicator attached to the Kromayer mercury-vapour lamp Unfortunately patients with discharging ears are only referred to the practitioner of physical medicine after years of treatment with ear-drops, &c I am convinced that many of the complications could be avoided if physical treatment was adopted from the first rather than as a last resort Treatment with the Kromayer lamp should be combined with local infrared irradiation which acts as a super fomentation and with general ultraviolet irradiation to raise the general powers of resistance

Wimpole Street, W 1 W Annandale Troup

MORE CERTIFICATES

Sir,—Neither the peripatetic correspondent in your issue for Nov 22 nor the general practitioner who wrote in the *Daily Telegraph* on Nov 24 has exhausted the varieties of "bits of paper" requested in the kind of confetti practice in which we are now engaged A small girl patient of mine has recently been a long time in plaster for congenital dislocation of the hips On removal of the plaster the orthopædic surgeon suggested that a rocking-horse should be bought for the child to aid in rehabilitation The parents duly went to a shop at a neighbouring town to seek a rocking-horse They were told that it could be supplied if a medical certificate were presented And so, solemnly I have written out a certificate that B requires a rocking-horse

Clynderwen, Pembrokeshire E Roland Williams

Prisoner of War —In a recent casualty list Lieutenant J E Readman, M R C S, R A M C, was posted as prisoner of war

Mobile X Ray Service —Fifteen mobile vans, fitted with X ray equipment, have been presented to the Ministry of Health by the British Red Cross and Order of St John of Jerusalem They will be stationed at selected hospitals in London and the Provinces so that calls from any part of the country can be answered It is not intended to use them for routine work but as reserve sets for an emergency caused either by raid damage or unexpected demands on a hospital's resources The vans will have women drivers and a radiographer will be attached to each unit, who will be appointed by the hospital at which the unit is stationed and who will work there while not engaged with the unit

Each van generates its own current for the X ray apparatus, which can be operated by cable up to 100 yd away, and has a dark room with films and developer

The Ministry of Health is anxious that full use should be made of these units, and application should be made to the hospital officer, or in the London sectors to the group officer

Medical News

niversity of Oxford

On Nov 22 the degree of B M was conferred in absence on A M Johns

University of London

Sir Ernest Graham-Little has been re-elected chairman of he council for external students for 1941–42

University of Wales

Prophit Tuberculosis Survey

The Royal College of Physicians of London proposes to appoint a scholar to conduct this survey into the incidence and progress of tuberculosis The appointment will be at the rate of £350–500 per annum, and special experience of tuberculosis is not essential Further particulars will be found in our advertisement columns

Czech Medical Examinations

At the request of the Czechoslovak Minister of the Interior and Education in London, the examining board in England of the Royal Colleges has undertaken to conduct a special final examination (second and third rigorosa) for the Czechoslovak MUDr degrees Part I (pathology and bacteriology) was held in London last week, when twelve candidates were examined The following were successful —

Artur Flach Jan Glaser Zdenek Pfeifer, Karel Skopek K J Su at Walter Tausig, Josef Voracek and Josefina Liebsteinova

Society of Apothecaries of London

The following, having completed the final examination, are granted the diploma of this society entitling them to practise medicine, surgery and midwifery M C Hannon, Birm , and F G Leekam, St Mary's

National Council for Maternity and Child Welfare

Lord Dawson will take the chair at a meeting to be held under the auspices of the council at 11 30 A M on Dec 10, at the Royal Institution, Albermarle Street, W 1, when Mr Ernest Brown will give an address on the care of mother and child in war time Prof Fletcher Shaw, P R C O G , will also speak

Royal Society of Medicine

On Wednesday, Dec 10, at 2 30 P M , Mr A Lawrence Abel will give his presidential address to the section of proctology He will speak on proctology's debt to living surgeons On Dec 12, at 2 30 P M , there will be a general meeting of fellows and afterwards Sir Almroth Wright, F R S will read a paper on the need for abandoning much in immunology that has been accepted as true

Royal Society of Arts

On Tuesday, Dec 16, at 1 45 P M , at the house of this society in John Adam Street, Adelphi, W C 2, Mr Maurice Ashby, D I C , will address the dominions and colonies section of the society on British Empire drug production

Seals, Salmon and Strychnine

In Scotland the depredations of seals in the salmon fisheries has been so great that the Home Secretary has had to make an exception to the prohibition of the sale of strychnine in the interests of the salmon Now amounts of strychnine up to 4 oz. may be bought for the purpose of killing seals

Ethical Pharmaceuticals Association

The sixth annual general meeting of this association was on Nov 11, and the following officers were elected for 1941–42 chairman, Mr W Beckley , vice chairman, Mr H R Napp , treasurer and secretary, Mr F G W Paige , members of executive committee, Mr J Angus (Bengue and Co) Mr G L Cooper (Coates and Cooper), Mr R F Edkins (Organon Laboratories), Mr A C Henry (Bayer Products) and Mr C W S Taylor (Ciba)

Pharmaceutical Society of Great Britain

On Thursday, Dec 11, at 2 30 P M , at 17 Bloomsbury Square, W C 1, the Harrison medal will be presented to Mr Thomas Tickle, F I C , public analyst for Devon Mr Tickle will afterwards deliver the Harrison lecture and has chosen to speak on the influence of analytical chemistry on pharmacy

Obituary

HENRY OWEN WEST

M D LOND F R C P D P H

ON Nov 20 Dr Henry West medical superintendent of Queen Mary's Hospital for Children at Carshalton, died without regaining consciousness three days after he had been struck down by a cerebral hæmorrhage His steadfastness keenness and high sense of duty had raised the standard of every institution where he worked, and these qualities were associated with the religious convictions which were the background of his life West was born in 1885 the son of the Rev J O West rector of St Philip's Bristol, and the eldest of a family of eleven He came to King's College London, in 1904 from Bristol University where he had passed the Inter B Sc He took a leading part in the Students Christian Union was a first-class hockey player and a useful bat For family financial reasons he had to qualify as soon as possible and early in 1909 after becoming a L M S S A he was appointed house-surgeon to Prof Albert Carless Later in the same year he took his M B and received senior house-appointments at the City Road Chest Hospital and at the Seamen's Hospital In 1913 he went to Queen Mary's Hospital for Children Carshalton as assistant superintendent, and there his interest in children's work and tuberculosis was stimulated Queen Mary's, under Dr Gordon Pugh was a recruiting-ground for tuberculosis medical officers and West soon took up this work and became T O for Kent He had taken his M D in 1912 and he continued to study obtaining the M R C P in 1914 and the D P H in 1916 He joined the R A M C. in 1917 and during his service in Salonika he was mentioned in dispatches But he contracted malaria and soon after his return to England was invalided out of the service

His appointment as medical superintendent of Princess Mary's Hospital for Children at Margate enabled him to return to the work in which he was most interested—children and tuberculosis—and to start his career as a hospital administrator During the twelve years he was there he became an authority on non-pulmonary tuberculosis in children and though primarily a physician he developed special skill in the treatment of surgical tuberculosis At his next job as medical superintendent of the Archway Hospital (L C C) his work as an administrator was recognised and he was soon promoted to St Giles' Hospital Camberwell (L C C) West had long felt that the staffs of teaching hospitals did not always appreciate good work done outside their walls and that the medical schools missed opportunities of teaching in public authority hospitals During his four years at St Giles' he was able to establish happy relations with his own old school Some of his staff taught at King's physicians and surgeons regularly brought their students to St Giles' and he recruited his resident medical officers as far as possible from King's In 1936 West became a fellow of the Royal College of Physicians and a year later he succeeded his old chief at Carshalton

He brought to this exacting and responsible post mature knowledge sound judgment and a high sense of responsibility for the children under his care He slept in his clothes at the hospital throughout the night bombing so that he could dash out at a moment's notice if anything untoward occurred as indeed it often did One night when a ward which had been damaged was being evacuated he was told someone had just noticed an unfamiliar hole in the ground West with extraordinary prescience realised it was probably a delayed action bomb and proceeded feverishly to get the children out of the two adjoining blocks Within a minute of the removal of the last child his intuition proved right There was a terrific explosion and the two wards suffered such damage that casualties would have been inevitable had anyone been in them He was properly proud that not one of his patients suffered any serious injury during the blitz

West married Miss Anne Finchett in 1913 and they had three sons who were all at Epsom College Two obtained scholarships to medical schools, and the youngest is a cadet at Dartmouth

CLAUDE CHURCHILL CHIDELL

M B B S LOND

Dr Claude Chidell who died at Hythe on Nov 18, in his 75th year, was one of the pioneers in the open-air treatment of tuberculosis As with so many others of his time his interest in the disease arose when he became a victim to it himself soon after qualifying, and having got the better of it in Switzerland and South Africa he studied methods at Nordrach and Friedrichsheim before he was invited in 1901 to take charge of Pinewood, then newly founded by a few far-seeing philanthropists for the treatment of early cases among the educated middle classes Here he found his métier, for his commanding presence, his sympathetic understanding of temperament, and his willingness to spend himself unstintingly, made him the ideal sanatorium chief But the strain was too much and after four years he joined a friend who was in practice at Arosa, and later—having in 1909 married Ethel Westall, daughter of William Westall, writer and journalist—had a home of his own at Broadstairs for children with surgical tubercle After his retirement in 1917 he settled in the Folkestone neighbourhood where he kept up his professional interests and revelled in bird and animal life as befitted a London University exhibitioner in zoology Through growing physical debility his mind remained clear to the end

Chidell was early left an orphan and was brought up in London by the parents of his Scots mother who was of Puritan ancestry He was educated at University College school and hospital qualifying in 1891 when he held house appointments at U C H and Birmingham fever hospital He wrote some useful articles on sanatorium methods but his memory is chiefly cherished in the lives of those whom he treated wisely and well

GERIATRIC DATA —A retired electrical engineer, still going strong at 86 has kept a careful log of his blood temperature pulse-rate, weight and so forth twice daily for some years He wants to know if these data would be of use to anyone

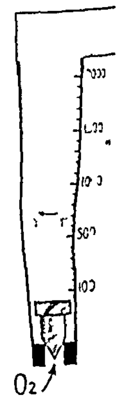
Notes, Comments and Abstracts

SICKLE-CELL ANÆMIA

SICKLE-CELL anæmia, of which a new case has recentl been described,[1] is a rare hereditary disorder of the blo almost exclusively affecting negroes It is characteri by the appearance in the blood from time to time of abnormal sickle-shaped red corpuscles which apparentl are rapidly destroyed in the body with resulting secondar anæmia The disease occurs in attacks with remission and apart from the hereditary factor nothing is known of its ætiology The diagnosis depends on the discovery of sickle-cells (drepanocytes) in the blood of the patient and of his relatives Sometimes they are found only after preliminary treatment of the separated red corpuscles by deprivation of oxygen, an observation which suggest that they *may be formed in the blood-stream* rather than in the bone-marrow The case lately reported from Cuba illustrates most of the features of the disea A negro boy, aged 13, was admitted to hospital sufferin from jaundice, enlarged liver and spleen and mitral incompetence Examination of his blood on two occasions showed 15% and 17% of sickle cells and hæmoglobin values of 75% and 47% The bone marrow contained no sickle-cells The blood of the patient parents and two brothers was examined All the people were apparently healthy but in *all* except one brother the blood after treatment showed sickle cell

FLOWMETERS FOR GAS OR LIQUID

ROTAMETERS have for many years been used in industry but it was not until 1937 that, at the suggestion of Richard Salt, technician to the Nuffield Department of Anæsthetics University of Oxford, they were adapted in a form suitable for anæsthetic apparatus Since then they have been widely adopted for measuring anæsthetic gases in this country The gas to be measured passes upwards through a specially drawn glass tube the axis of which must be vertical The bore of the tube is in the form of an elongated cone with its widest diameter uppermost (see figure) The range of rates of flow of the gas to be measured determines the shape of the cone The bobbin, usually made of aluminium, has small vanes cut in its free edge The stream of gas impinges on the vanes and causes the bobbin to rise and spin round freely on its vertical axis thus eliminating errors due to friction of the bobbin against the walls of the glass tube The pressure loss due to the presence of the bobbin is constant for all positions in the tube The more the control valve is opened the higher is the bobbin forced, and the greater is the area of escape for the gas between the bobbin and the meter tube If the tube is mounted in the truly vertical position these meters are capable of readings of great accuracy



Rotameters are made for a wide variety of purposes and for flows ranging from 20 c cm of liquid or 50 c cm of gas up to 100 litres liquid or 1000 litres of gas per min The makers are the Rotameter Manufacturing Co Ltd , of Portslade, Sussex

SUPPLIES OF ALBUCID —British Schering Ltd inform us that, although sulphacetamide appeared in class B of the supplement to the M R C memo on economy in drugs, they are regularly supplying Albucid of British manufacture and have so far been able to meet promptly all demands for that compound

A GROUP OF HEAD INJURIES

JOHN E. A. O'CONNELL, M.B. LOND., F.R.C.S.
NEUROSURGEON, E.M.S.

A REVIEW of the records of 250 cases of head injury consecutively admitted to the neurosurgical unit of an E.M.S. hospital suggested that an analysis of the material might merit publication. Although the number of cases is small when contrasted with the total number of head injuries treated throughout the country during the same period, yet it is large and the material is varied when compared with peace-time standards. In addition, more benefit may be derived from the personal study of relatively small groups of cases at individual centres than from the analysis of large numbers of records by those who have themselves examined but a small proportion of the cases.

A number of the head injuries of ordinary practice are included in this series but many more of the patients were war casualties, some wounded military evacuated from abroad and a larger number of people wounded in this country in air-raids. The centre from which this report emanates is a base hospital so that the group of patients is a selected one. A number of the most serious injuries would die before their transfer to the base could be effected, and the less severe injuries would be discharged from the hospital to which they were first admitted without ever reaching the base. Furthermore, although there is a natural tendency for patients showing complications to be transferred to the base over 200 of the patients were admitted because of a recent head injury, and in spite of the selection it is believed that the figures have a general application.

The term head injury is here used instead of the more cumbersome one of cranio-cerebral injury, to denote cases of injury to the brain or its coverings. Injury to the face and jaws is therefore excluded unless it be associated with evidence of trauma to the brain. The cases will be considered in two groups. First, open head injuries in which there is present *either a scalp wound, a compound fracture* of the skull, or actual cerebral penetration. Secondly closed head injuries in which, although the brain is injured its superficial coverings remain intact. The main value of such a classification is that it suggests the important fact that open injuries are associated with a risk of infection of the meninges and brain which is absent in closed injuries. The number of patients with open head injuries was 148, and with closed head injuries, 102.

Open Head Injuries

The varieties of open injury which have been dealt with were as follows:

Scalp wound	54	Cerebral penetration—	
Compound fracture of skull—		(1) uncomplicated	22
(1) fissured	37	(2) cerebral fungus	11
(2) depressed	20	(3) cerebral abscess	4
		Total	148

SCALP WOUNDS

It is perhaps not sufficiently emphasised that most scalp wounds are lacerated and not incised. It is not surprising that a force great enough to split the scalp by compressing it against the skull is often great enough to damage the underlying brain. In the table it will be seen that evidence of such cerebral injury is frequently present. Two-thirds of the patients admitted with scalp wounds were unconscious for shorter or longer periods and 15% of them showed evidence of focal cerebral damage, by which is meant such manifestations as a hemi- or mono-plegia, or an area of sensory loss of cortical type. As further evidence of the intracranial damage which may be associated with a scalp laceration may be taken the results of lumbar puncture. In only 5 of the cases was it considered necessary, but 4 of these showed definite abnormality of the cerebrospinal fluid (blood or a high protein). Had lumbar puncture been carried out as a routine there can be no doubt but that abnormality would have been detected in many other cases.

After the last war Jefferson (1919) reported signs of localised brain damage in almost a third of a group of scalp injuries which had been under his care. Many of these patients had gunshot wounds of the scalp and it seems that in such wounds the risk of brain damage is greater than in lacerated wounds. Its cause is in part the extreme violence of the injury and in part is doubtless similar to that of the paraplegia which sometimes follows the passage of a bullet close to but not through the spinal canal. More recently McKissock and Brownscombe (1941) have emphasised the frequency with which scalp wounds are associated with evidence of cerebral damage. Cairns (1941) has also drawn attention to the risk of infection spreading through the intact skull and dura from gunshot wounds of the scalp. It has of course always been recognised that any infected lesion of the scalp may lead to infection of the skull and intracranial contents. For this reason it is felt that scalp wounds can justifiably be considered under open injuries.

INCIDENCE OF NEUROLOGICAL DISTURBANCE AND FATALITY-RATES IN OPEN HEAD INJURIES

Type of injury	Total	Cerebral concussion	Evidence of focal brain damage	Deaths	Remarks on fatal cases
Scalp wound	54	36 (66%)	8 (15%)	1 (2%)	No operation. Uræmia
Compound fracture—					
(*a*) fissured	37	28/30* (93%)	4 (11%)	1 (2.7%)	A severe crushing injury
(*b*) depressed	20	11/17* (65%)	6 (30%)	0	
Cerebral penetration	37	16/28* (57%)	26 (70%)	3 (8.1%)	Two died without operation. One postoperative death from senile heart disease

* In the remaining cases the record was insufficient to decide whether concussion was present.

In treatment the importance of adequate exploration of scalp wounds cannot be over-emphasised. This is perhaps especially true of the short wounds which may conceal a penetration of the skull or brain. It is obvious that a proper débridement of a contaminated wound can only be carried out when it is fully explored. Two of the cerebral abscesses in this series arose because what were in reality penetrating wounds of the cerebrum had been regarded as trivial scalp wounds when the patient received his early treatment at first-aid post or hospital. When a large number of casualties are suddenly admitted to a hospital in an area which has been subjected to a heavy air-raid such mistakes are understandable. But they are very serious and would be avoided if final treatment of the wound were delayed and the early treatment confined to securing hæmostasis which can be obtained by the introduction of a very few sutures after the wound has been dusted with sulphanilamide. Thorough exploration, debridement and careful suture can be delayed for many hours in such cases.

Since wide excision of the margins of a scalp wound is never necessary there is usually little difficulty in approximating the margins of the wound accurately by suture. Occasionally—for example, in tangential gunshot wounds—the injury may entail a considerable loss of scalp tissue. When such loss of tissue has occurred it will often be possible to make it good by wide mobilisation of the scalp and the sliding of a flap over the defect. Occasionally the loss of tissue may be so great that this is impossible. If the denuded outer table of the skull is allowed to form the base of an ulcer, healing will be greatly delayed, for epithelialisation can occur only over a base of healthy granulation tissue. Such a base will usually be obtained only when the outer table has sequestrated and the diploic granulation tissue is exposed. The long delay necessary to permit such sequestration can be avoided if at the time of the original operation a number of drill holes is made into the diploe of the exposed area of bone (Porter and Shedden 1922) thus will allow of its rapid covering by granulation tissue derived from the diploe and epithelialisation of the area will thus be greatly accelerated

COMPOUND FRACTURE OF SKULL

Although variations in the structure of the skull itself may be a factor tending towards the production of a fissured fracture in one case and a depressed fracture in another it seems certain that the manner of application of the force to the skull is the usual deciding factor It is generally agreed that a depressed fracture results from the action of a localised force of considerable intensity such as a blow on the head with a small hard object Such violence will produce, in very many cases, a laceration of the scalp and then a localised fracture of the skull, often with indriving of the bone fragments A fissured fracture may result from less severe degrees of the same kind of violence but is usually the result of a force applied to a wide area of skull As a result of this the whole skull is deformed and when the deformation has been carried beyond the limits of the elasticity of the bone a fracture arises and tends to spread along the mechanically weakest portion of the skull—its base Trotter's classical description has led to the general acceptance of these statements

It might be expected that the neurological disturbance would differ in the two types of fracture, and in the table it will be seen that this is actually so Almost all the cases of fissured skull fracture show a period of unconsciousness immediately after the receipt of the injury, whereas this was present in only two-thirds of the cases of depressed fracture On the other hand, while fissured fracture was associated with evidence of focal damage to the brain in 8% of cases there was evidence of such damage in 30% of depressed fractures It seems clear that fissured fractures are associated with evidence of generalised cerebral damage more often than are depressed fractures, while they are much less often associated with evidence of focal nervous disturbance

The occurrence of a leak of cerebrospinal fluid through a skull fracture to the exterior is important because it is clear evidence of a communication between the subarachnoid space and an infected surface area It is of interest that the fractures of the vault in this series, and therefore all the depressed fractures, were not associated with such leakage, which is not uncommon in fractures of the base of the skull Several reasons for this difference at once suggest themselves The dura mater at the vault of the skull is but loosely adherent to the bone, at the base the attachment is very firm A fracture of the vault, even with considerable depression, will often not tear the dura which separates from the bone and slides beneath it, while this may not be true in children it is certainly true in adults Any separation of a basal fissure will be at once associated with a tear in the dura, and all that is then necessary for the occurrence of a leakage of cerebrospinal fluid is an associated tear in the delicate arachnoid No doubt the large size of the basal subarachnoid channels compared with those over the convexity of the hemisphere is another reason for the different incidence of leakage in fractures of the two types Perhaps also gravity tends to maintain a leak at the base when it would have a contrary effect elsewhere

There is difference of opinion as to the correct treatment of a leakage of cerebrospinal fluid after a head injury While leakage may take place into both the nose and the ear, in the latter case it probably always ceases spontaneously The problem is, therefore, that of treating traumatic cerebrospinal fluid rhinorrhœa Some think that the defect through which the leak occurs should be closed by early operation in all cases—the argument being that even when the leak stops spontaneously subsequent meningitis is a definite risk But it is difficult to see why the scar of an operative closure, even if it includes a fascial graft, should be a stronger barrier to the spread of infection than the scar resulting from natural healing In the present series there are 4 cases of cerebrospinal rhinorrhœa In 3 the leakage ceased spontaneously—in one patient after as long as five weeks

In the fourth patient the leak continued for seven weeks During this period she slowly recovered consciousness and after this had recurring attacks of meningeal irritation, in which lumbar puncture showed many polymorph leucocytes in the cerebrospinal fluid but no organisms sterile culture In view of the obvious threat of an operative closure was carried out An intradural was used The opening in the dura mater clothing posterior part of the cribriform plate was seen and with a graft of fascia taken from the thigh The closed after generous local application of sulphanilamide After this operation the leakage ceased and there has been recurrence up to the present

A follow-up of a considerable number of these some treated conservatively and some by early oper is necessary before a definite decision can be reached to the correct treatment of traumatic cerebrospinal rhinorrhœa in its early stage

Two further points in the treatment of compound skull fractures may be raised The value of chemotherapy in preventing the onset of meningitis in case where the subarachnoid space has been opened by the injury is obvious It has been used in a large number of cases and in all those in which there was leakage of cerebrospinal fluid, whether from nose or ear During operations on compound depressed fractures hair and other foreign material are sometimes found between the bone and the dura mater Adequate treatment of any compound fracture in which more than the slightest degree of depression is present, and in which the pericranium is torn, will obviously necessitate the removal of depressed fragments of bone and of underlying foreign material and the examination of the dura Levering of fragments into position through a trephine opening placed on one side of the depression cannot allow of adequate exploration or debridement

CEREBRAL PENETRATION

In the table the neurological disturbance which follows penetrating cerebral wounds is contrasted with that which follows other types of open head injury It will be noted that the incidence of loss of consciousness is similar to that in depressed fractures and scalp wounds and much lower than in fissured skull fractures On the other hand the incidence of focal cerebral damage is—as might be expected—higher than in any other group, amounting to 70% This high figure is clearly associated with the actual passage of a missile into the brain, and the effects of this direct injury to the cerebral tissue may be permanent or transitory

The importance of the dural envelope becomes obvious when penetrating wounds are considered It is the final barrier to the spread of infection to the leptomeninges and brain Moreover, in the vast majority of cases a body which penetrates the dura will also penetrate the brain, causing laceration of cerebral tissue Such penetration will be associated with the risk of immediate focal neurological disturbance and perhaps epilepsy later The risk of both these sequelæ is greater in penetrating wounds than in any other group of head injuries It has already been pointed out that the dura mater is so strong that in depressed fractures of the vault of the skull it will often prevent penetration of the brain even when the depression is of considerable degree Occasionally a foreign body which has penetrated the skull will be held up by the dura in a similar way and it is noticeable that when a foreign body such as a bomb fragment does penetrate the dura it usually passes deeply into the nervous tissue—perhaps until its passage is blocked by some more resistant tissue such as a dural septum

Penetrating wounds will usually be associated with the presence of foreign bodies within the brain Focal signs will in most of such cases be due to the injury done by the foreign body to nervous tissue and perhaps also to cerebral blood-vessels in its passage through the brain Removal of the foreign bodies cannot therefore lessen any focal nervous disturbance, indeed attempts at removal of deeply placed foreign bodies may, by further damaging nervous tissue, have a contrary effect On the other hand, the complete debridement of any wound implies the removal of all foreign material A piece of metal or bone left in the cerebrum may lead to infection of the brain Many examples of abscesses arising in connexion with foreign bodies are known and often in such cases symptoms do not appear for many years

The procedure adopted in this series has been to excise the scalp wound and then the margins of the bone defect bloc as described by Cushing (1918) By means of ction and irrigation through a soft rubber catheter e track is cleared of blood-clot, necrotic brain and iall foreign bodies such as bone chips If metallic reign bodies are easily localisable and removable this done If not the foreign material is allowed to remain situ and the wound closed, drainage being used or not cording to the interval between receipt of the wound d the operation It is felt that possible complications ising from retained foreign bodies can be dealt with as ey arise

In this series there were 24 patients with intracerebral reign bodies The foreign material was bone in 9 ses, masonry in 1 and fragments of bomb or shell in 4 In only 2 instances was the metallic body removed, ut all the other foreign material was removed This as partly because the non-metallic types of foreign body end to be superficially placed and also because they are erhaps more liable to harbour infection, associated as hey are with laceration of scalp and comminution of the kull The wound of a bomb or shell fragment is often y comparison small and clean cut

It will be noted that there were 11 cases of cerebral fungus The frequency of this complication of a penetrating wound depends on several factors, among which may be mentioned a very long delay between receipt of the wound and the institution of treatment (48 hours or more), the destruction of a wide area of scalp, skull and brain in a gunshot wound of tangential type, and sometimes inadequate treatment in the early stages When brain tissue is exposed in the floor of a wound healing can only take place by the growth of epithelium over the exposed cerebrum This in turn can only occur when the exposed brain tissue has been replaced by healthy granulation tissue During the time necessary for this process there is a constant tendency for progressive protrusion of the cerebral tissue through the defect in the dura mater This tendency made cerebral fungus a much feared complication at one time but now, with modern methods of reducing intracranial pressure—posture, dehydration and lumbar puncture—and chemotherapy to combat the risk of meningeal infection, the condition can usually be readily dealt with The 11 patients in this series all made a good recovery

Of the patients with penetrating wounds 4 were treated for cerebral abscesses, 2 of these resulted from inadequate exploration of scalp wounds at the hospitals at which the patients had first received treatment Here the evidence of meningeal reaction and the progression in focal neurological disturbance made the diagnosis obvious In 2 other cases the abscess was found unexpectedly The abscess was treated by tube drainage in each case with healing and recovery of the patient The ease of localisation and slow development of the abscesses in the series, together with the possibility of always avoiding contamination of the meningeal spaces by instituting drainage through an area in which they were completely obliterated by scarring, probably accounts for this happy result

Closed Head Injuries

Cerebral concussion was present in all the patients with closed head injuries—indeed it is cerebral concussion following a blow on the head which admits a patient to the group Sometimes, of course, a blow on the head which does not produce unconsciousness produces subdural hæmorrhage and later focal neurological signs, but there has been no such case in this series Of the 102 patients with closed head injuries, 13 present evidence of a focal lesion of the brain Such damage was more common in the closed injuries associated with skull fracture than in those without fracture, the incidence being 29% in the former and 8% in the latter This difference is no doubt due to the more severe injury which produces fractures

Evidence of generalised neurological disturbance—i e, cerebral concussion—was present in all the closed injuries and almost all the open fissured fractures, but in about two thirds only of the scalp wounds, depressed fractures and penetrating wounds Not only so, but the duration of unconsciousness and amnesia was on the whole greater in the closed injuries and open fissured fractures than in the other groups Focal neurological disturbance occurred in 10–15% of scalp wounds, closed injuries and open fissured fractures, in depressed fracture its incidence rose to 30% and in cerebral penetration to 70% These figures illustrate the difference between the more generalised deformation of the skull which produces closed injuries with cerebral concussion and the localised violence which produces cerebral penetration and depressed fracture with focal brain damage They are in accordance with Trotter's (1932) description of the mechanism of skull fracture In general it may be said that two distinct types of force may be responsible for a head injury—the one a strictly localised force which produces localised damage to scalp, skull and perhaps brain, the other a more generalised force which produces a generalised disturbance of nervous function The exact method by which the latter disturbance is produced remains unsettled In many instances injury will result from a combination of the two types of force—e g, compression maximal at one point—and under these conditions focal and general neurological disturbance may occur together

It is the focal damage which occurs not infrequently in depressed fractures which renders those who have had such an injury liable to develop epilepsy, the depression of the bone fragments is, like the focal cerebral damage, due to the force of the original injury Removal of the bone fragments, at one time popular in the treatment of such cases, therefore offers little prospect of curing the epilepsy This point is well illustrated by one of the cases in the series

A young man was struck in the right parietal region by a fragment of incendiary bomb He suffered no immediate ill effects and the small scalp wound received no treatment Four days later he developed left sided Jacksonian convulsions General and neurological examination showed no abnormality A skull X ray showed a depression of the inner table of the skull of 3 mm and a metallic fragment lodged superficial to the depressed fragment A small osteoplastic flap was turned down and the depressed fragment of skull and the foreign body removed from its deep surface There had been no penetration but owing to its being extremely tense and non-pulsating the dura mater was opened From beneath a dark spot on the cortex half an ounce of dark thick blood clot was evacuated This completely relieved the tension and there has been no recurrence of the attacks

HEADACHE AND THE POST-CONCUSSIONAL SYNDROME

While headache is a very frequent symptom in all types of head injury it is probably more frequent and more severe in the closed injuries than in any other group Correct treatment in the early stages is of great importance since if the headache continues for many weeks after the injury cure may be exceedingly difficult Here lumbar puncture may be of assistance both as a therapeutic measure and as a guide to treatment Pressure estimation will show whether the headache is associated with high or low intracranial pressure and suitable postural treatment and regulation of the fluid balance can then be instituted In many cases blood is present in the cerebrospinal fluid It is almost certainly a factor in the production of headache and is perhaps also responsible for other symptoms Lumbar puncture will, by removing blood, relieve these symptoms Again, it seems certain that at least occasionally blood produces an inflammatory reaction in the meninges which may be of such intensity as to obstruct the circulation of cerebrospinal fluid and even produce a hydrocephalus some time later Its early removal should minimise the risk of such complications

After careful treatment of cases of head injury along lines which are now well recognised the early headache will in many cases quickly disappear In cases in which it persists, or having cleared up recurs when the patient is subjected to the stresses of ordinary existence, the problem becomes very different In many such cases general physical, neurological and laboratory examinations are entirely negative Where pneumoencephalography has been carried out in cases of this type in this series it has usually shown no abnormality and has rarely had the beneficial effect on the headache which has been claimed for it While at first sight it appeared that the post-traumatic headache of chronic type was more frequent after closed injuries, more careful examination of the figures revealed that its incidence was about the same in all types of injury when calculated on the basis of those patients who had lost consciousness Approximately 20% of the patients who had been unconscious in each of the groups of closed head injury (many of these admitted months after the injury), compound fracture, and cerebral penetration showed this sequela It seems then that one important factor predisposing to the complication is loss of consciousness, so that the syndrome of headache, vertigo, tinnitus, &c is better named post-concussional than post-contusional

Apart from this nothing can be said as to the ætiology of the commonly recurring symptoms of the post-concussional syndrome There is almost certainly a lesion in the brain to account for the syndrome in some cases, but it is perhaps no more demonstrable than that of cerebral concussion itself or of "idiopathic" epilepsy Indeed it may be even more difficult to demonstrate since electroencephalography will show abnormal electrical activity in the cortex of the epileptic brain, whereas no such change is to be found in many cases of post-concussional syndrome Whether or not there be a lesion in the brain to account for the syndrome it does seem that constitutional factors are important in its development, for in many patients the personal and family history will show evidence of functional nervous disease

Over 20% of the definitely selected group of closed head injuries exhibited cranial-nerve palsies Every nerve with the exception of the eleventh was affected although the third and sixth nerves and the seventh and eighth were most commonly involved While a longer period is required to follow up the cases it would seem that the prognosis is on the whole favourable Certainly it seems that injury to the purely motor cranial nerves occurring in association with skull fracture is as likely to be followed by spontaneous recovery as is a radial-nerve lesion complicating a fracture of the humerus

It has been pointed out above that 13% of the closed head injuries was associated with evidence of focal brain injury It has also been suggested that the type of force which produces a generalised cerebral injury will often exert its maximum effect at one point—hence the origin of the local cerebral injury This does not necessarily mean that the focal damage is in relationship with a fissured fracture (as it probably always is in depressed fractures) It is well known that the injury to the brain by contre coup may be much more severe than that beneath the skull at the point which received the direct trauma The actual type of lesion which is responsible for the signs of focal damage will vary and on its pathology will depend the severity of the signs, their duration, the ultimate prognosis and the correct treatment of the individual patient For example, 2 of the patients had chronic subdural hæmatomata, evacuation of which resulted in the complete disappearance of the neurological signs

It may be well to emphasise again that this is a selected group of cases The scalp wounds and closed injuries admitted to the neurosurgical wards were the more serious ones—the less severe injuries being admitted to general surgical wards or perhaps never evacuated to the base at all This means that the incidence of focal nervous disturbance in both groups is higher than would be the case in an unselected group of patients On the other hand from the point of view of mortality statistics it may again be pointed out that the severest injuries, dying within hours of the trauma, would never reach the base hospital either, so that mortality figures will tend to be too low The mortality in the various groups of open injury is set out in the table Of the 101 closed head injuries 63 were relatively recent injuries, the others being cases of post-concussional syndrome, &c There were 3 deaths in these 63 cases giving a fatality-rate of 4 8%

Summary

A consecutive series of 250 head injuries admitted to an E M S neurosurgical centre is analysed

Since many scalp wounds are lacerated and not incised there is often evidence of associated brain damage

Scalp wounds must be adequately explored When circumstances prevent immediate exploration the final treatment can and should be delayed until it can be carried out thoroughly

Since wide excision of the margins of a scalp wound is never necessary its suture will usually present little difficulty When a defect in the scalp is present it often be closed by the mobilisation of scalp flaps this be impossible drilling of the exposed outer table the skull will promote the rapid covering of the bone granulation tissue and thus speed epithelialisation

Adequate debridement is important in com depressed fractures of the skull

Leakage of cerebrospinal fluid is not uncommon fractures of the base of the skull but was not seen fractures of the vault in this series Leakage into ear probably always ceases spontaneously A decision as to the correct treatment of cerebro rhinorrhœa cannot be given, but in the early traumatic period a conservative attitude seems justifi

Deeply placed foreign bodies, which are usually will rarely in themselves produce symptoms or Ill-advised attempts to remove them may lead to sub brain damage and permanent defect in nervous funct

Eleven patients who developed cerebral fungus recovered Treatment is mainly by measures designed to lower intracranial pressure

Chemotherapy with the sulphonamides, both local and general is of value in all open injuries

Depressed skull fracture and cerebral penetration result from a localised impact of considerable violence, whereas other types of open and all closed fractures are more often the result of widespread force which produces a general deformation of the skull This may explain the high incidence of focal cerebral damage, often without cerebral concussion, in the former types of injury, and the high incidence of cerebral concussion without focal cerebral damage in the latter group

Lumbar puncture is valuable for both diagnosis and treatment in suitable cases of closed injury

Efficient treatment in the immediate post-traumatic period may be important in preventing the post-concussional syndrome The psychological background of the individual patient has also an important bearing on the occurrence of the syndrome

From the experience in this series the prognosis in post-traumatic cranial-nerve paralysis seems usually to be good

Focal signs are not uncommon in closed head injuries Not every patient showing such signs, even when they are severe, will require operative treatment

I wish to acknowledge my gratitude to Prof Paterson Ross for the opportunity of investigating and treating the majority of the patients included in the series and for his help in many other ways

CLOTTING AND FILTRATION OF CITRATED PLASMA

MONTAGUE MAIZELS, M D LOND, F R C P
(*South-eastern London Blood Supply Depot*)

UNFILTERED citrated plasma has proved of great value in the treatment of shock Its disadvantage is that even with the most careful processing it sometimes becomes infected, and since sterile unfiltered plasma is naturally cloudy infection cannot be detected by observation alone—at least until the growth is very heavy For this reason filtration has special advantages, it considerably reduces the risk of infection and leaves the material clear so that infection can readily be detected by the appearance of opalescence Filtered plasma appears to have the same therapeutic value as unfiltered

Unfortunately, the passage of plasma through Seitz bacterial filter pads presents difficulties Clotting is apt to occur and to limit the amount of fluid that can be passed through a filter This clot develops sooner or later in the filtered material even when it is stored at room temperature The change is hastened by cold, and frosty weather is usually followed by a crop of clotted samples The mechanism of this clotting is obscure and differs from that of physiological clotting It is discussed by hby Buttle and Whitby (1940) who state that it is to the crude asbestos present in all makes of bacterial er pads it is certainly not due to calcium derived from pads since the calcium content of plasma before and er filtration is almost unaltered Bushby Buttle d Whitby (1940) find that clotting can be diminished frequently washing the filter pads with a solution of stic soda (N/30) and sodium citrate This procedure dified by Stanbury (unpublished) is said to give a more ble plasma which remains clear for months But even e faint opalescence and small tags of protein material y appear and gross clotting follows in time , and it is be expected that an unstable protein like fibrinogen uld have a special tendency to denature For these asons it seems likely that plasma which has had its rinogen removed and is converted into serum would be ore stable than unclotted plasma

The difficulties of storing filtered plasma have resulted an extensive use of filtered serum, which has the same nical value as filtered plasma, is equally free from ndesirable reactions and is much more stable Nevertheless filtered plasma will still have to be used , severe emorrhage is common in air-raid casualties and large tocks of citrated whole blood have to be available onsequently there is a steady potential supply of citrated lasma that must be salved The ideal method of storing his material is to dry it immediately after filtration and o secure a perfectly stable product At present, however, it is not possible to do this on a sufficiently big cale to deal with all the plasma available and a method s still needed by which filtered citrated plasma can be onverted into a product which though fluid is still quite table

Two methods of clotting citrated plasma have already been reported Picken (1941) clots plasma by the addition of serum the action apparently being ascribed to preformed thrombin present in the serum He finds that it requires five volumes of serum to clot one of plasma In our opinion this is not an economical method and is quite impracticable except at blood-depots where large supplies of serum are available Clegg and Dible (1940) add calcium chloride to citrated plasma until there is a sufficient excess of calcium over citrate to cause clotting An addition of 60 mg per 100 c cm is needed and the final overall calcium content varies between 65 and 80 mg per 100 c cm The method is simple and the authors state that in spite of its high calcium content the serum is non-toxic · this will doubtless be so in most cases but on general grounds it would appear undesirable to issue material containing so much calcium if a product with a lower calcium content became available

METHOD

The method described here combines the processes of Clegg and Dible (1940) and of Picken (1941) with an apparent economy in both calcium and serum the one seeming to reinforce the other so that the total effect of the two combined is in excess of what might be expected from each separately The mixtures of serum, plasma and calcium shown in table I will all clot completely Plasma used was derived from time-expired blood prepared according to the present Medical Research Council method (1940) 100 c cm 3% sodium citrate, 20 c cm 15% glucose solution and 420 c cm blood

TABLE I—CALCIUM REQUIRED TO CLOT MIXTURES OF SERUM AND PLASMA

Serum (parts)	Plasma (parts)	Calcium added	Final overall calcium
		mg per 100 c cm	
2	1	9	18
1	1	15	23
1	1 5	19	27
1	2	23	31
0	1	46	53

It is not possible to state without clinical trial which of these mixtures is most suitable for use The first four all have reasonably low calcium contents and the second and third are economical of serum The method used by us for a mixture of 1 5 parts of plasma and 1 of serum (the third in the table) is as follows

A concentrated solution of calcium chloride is prepared and its calcium content must be estimated either as calcium or as chloride This solution is diluted until it contains 10 g Ca or 27 8 g $CaCl_2$% A Winchester-quart bottle capped with a perforated screw top and rubber washer is then taken and two marks are made on its outside, one corresponding with the 1200 c cm and the other with the 2000 c cm level Some glass beads and 3 8 c cm of the calcium chloride solution are placed in the bottle, which is capped and autoclaved When the bottle is cold it is filled with plasma and serum and any technique may be used which affords complete asepsis First plasma is run in from the bottles of time expired blood up to the 1200 c cm mark Separation of plasma from cells is quite crude and may include the intermediate " buffy " layer and a proportion of erythrocytes Next, serum is run in to the 2000 c cm mark. Here also separation is complete; every trace of serum is removed even at the expense of removing a number of red cells Cellular elements (possibly platelets) present in the mixture are mainly included in the clot and they appear to aid its contraction The contents of the Winchester having been mixed the bottle is left inverted in a warm room (22° C) overnight and then for two days in the cold room After this time, a small compact clot holding most of the red cells in the mixture will be evident and the clot-free fluid which contains few erythrocytes may be separated from it almost completely

There are some who may object to leaving the plasma-serum mixture overnight at room temperature on the grounds that the growth of bacteria will be encouraged. If an aseptic technique is followed this objection is not valid However, if desired. it will probably suffice to leave the material in a warm room for four hours and then for several days in the cold If this is done it is likely that a large bulky clot will form and not contract. Nevertheless it is easy to obtain most of the fluid from the bulky clot by slinging the inverted bottle from the ceiling and allowing the fluid to drain for two or three hours from a needle thrust through the perforated cap and rubber washer It will of course be necessary to insert a second and longer needle into the inverted bottle to provide an air-inlet The glass beads prevent the clot from blocking the outlet needle and also strain off a proportion of free erythrocytes When the clot-free fluid has been collected it is strained through a tamped-down pad of Perfecta Paper pulp (a procedure in use at the Wellcome Research Institute) and then passed through a bacterial filter pad The calcium content of the final product is about 28 mg per 100 c cm

Using such an artificial serum, more than 60 c cm filtrate was obtained per 1 sq cm of pad, and filtration was still proceeding freely when the experiment was discontinued No trace of clotting appeared in the filtrate or in the pad and the filtrate remained bright, transparent and free from clot for over fourteen weeks in the cold room Since cold accelerates clotting due to filtration it may be presumed that this filtered material when stored at room temperature will remain as stable as filtered serum That the addition of a large excess of calcium had no effect on the product is further evidence that remote clotting is unlikely

The immediate effects of filtration on ordinary citrated plasma and on plasma-serum-calcium mixtures were as follows The first 500 c cm of filtered plasma collected slowly and a clot appeared immediately , the next 100 c cm filtered very slowly and clotted at once , filtration then ceased owing to the presence of clot in the filter pads In the case of fluid derived from a mixture of plasma serum and calcium on the other hand 6500 c cm. filtrate was collected quickly and without any clotting The area of the filter pad was the same in each case—80 sq cm

The total calcium of the preparation just described was 28 2 mg per 100 c cm which is considerably less than that of Clegg and Dible's (1940) material and is not likely to cause serious toxic effects The material, moreover has the advantage that it provides a stable fibrinogen-free product and although serum has to be used in the process the therapeutic effect of this serum is added to that of the plasma From one aspect indeed there is a saving of serum since during the ordinary process of separation from blood-clot it is usual to remove only the cell-free upper portion of serum and to leave a fairly considerable cell-rich residue behind which is usually wasted When however serum is used to clot plasma, the whole serum may be used including the dregs It is also possible to manage the initial serum separation so that the large clear portion is directed into one vessel for primary filtration and storage, while the small blood-stained residue is diverted into a second vessel and used to clot a plasma and calcium-chloride mixture A further advantage of the present method lies in the decrease of agglutinating titre resulting from mixing time-expired group O plasma with serum from groups A, B and AB The process is certainly more complicated than the filtration of plasma in that the mixing of serum and plasma involves an extra manipulation, but once this has been accomplished filtration is simple and straightforward, whereas the standard filtration of unclotted plasma demands the frequent washing of pads to secure a reasonably stable product

No definite figure can be given for the amount of calcium required to clot a given mixture of serum and plasma The figure will vary with the amount of thromboplastic materials in plasma and serum and also with the relative amounts of citrate and calcium present in the plasma after storage The decrease in prothrombin which occurs in old plasmas may call for extra calcium On the other hand, during storage citrate and calcium may diffuse into the red cells from the plasma, whose citrate and calcium contents will fall The amount of calcium that must be added to produce clotting will then depend on the decrease of citrate relative to that of calcium

In view of possible variations in plasma citrate and calcium, this question was considered more fully There is in a bottle of blood 100 c cm 3% citrate, 20 c cm 15% glucose and 420 c cm of blood containing about 185 c cm of cells and 235 c cm of plasma If observations are made immediately after collection, before citrate has had time to diffuse into the erythrocytes, the 3 g sodium citrate will be distributed between 100 c cm citrate, 20 c cm glucose and 235 c cm plasma—that is, 3 g in 355 c cm or ·845 mg per 100 c cm It is known that during storage blood cells swell owing to the entry of water and salts if penetration of citrate is relatively less than that of water, plasma citrate will rise, if the entry is more, plasma citrate will fall

Plasma citrate was estimated by the method of Pucher, Sherman and Vickery (1936) Hydrogen peroxide was preferred to ferrous sulphate for decolorising the potassium permanganate and several standards were set up They consisted of stored serum to which the appropriate amounts of citrate solution were added After twelve days' storage, ten plasmas contained 780 mg sodium citrate per 100 c cm, with a standard deviation of ± 55 mg per 100 c cm In another experiment, two plasmas separated from a sample of blood immediately after collection contained 825 and 850 mg sodium citrate per 100 c cm Ten days later, the contents were 850 and 770 mg per 100 c cm Similar observations apply to calcium serum and undiluted plasma contain about 10 mg Ca per 100 c cm, 235 c cm plasma diluted with 120 c cm of citrate glucose solution should contain 6 6 mg Ca The actual figures for two fresh citrated plasma were 6 6 and 6 8 mg per 100 c cm, for five plasmas stored between 5 and 10 days 6 8 ± 0 2 mg per 100 c cm, and for five plasmas stored between 11 and 16 days 6 5 ± 0 3 mg per 100 c cm

It may therefore be said that such citrate and calcium as leaks into red cells during storage, in the absence of mixing and shaking, is accompanied by a more or less proportional amount of water In agreement with this, it has been found that the amount of calcium required to clot a mixture of plasma and serum did not vary during the first twelve days of storage

It must also be noted that clotting is a relative process depending on time and temperature A mixture showing moderate clotting at twenty-four hours may show considerable clotting at seventy-two hours, unless it is kept in the cold, when the increase of clotting with time is very slow If, then, a mixture of plasma and serum is kept for a longer time at room temperature, it is possible that less serum or calcium might be used than is indicated in table I But in our experience, if clotting is not adequate after sixteen hours, subsequent change, even though considerable, is rarely complete and such fibrinogen as remains will be turned into fibrin after passage through the bacterial filter pads and show itself as a slight diffuse cloudiness or as tags of protein in the filtrate

DISCUSSION

The figures in table I for the clotting of plasma in vessels allow a certain margin of safety, the calc being about 2 mg per 100 c cm higher than the experimental value found to be effective The ex ments on clotting in bulk were based on earlier work which one ounce "flats" were used for the sake economy It required relatively less calcium to cl these smaller amounts of plasma, possibly because t process is hastened by the nearness of the vessel w to all parts of the plasma The data for clotting sma amounts of plasma-serum mixtures are rather mo accurate than those set out in table I and allow theoretical consideration (table II)

A very small change in the amount of calcium adde may make all the difference between slight and complet clotting In the second experiment in table II the simp mixture of plasma and serum gave a diffuse tenuo clot, the addition of 1 5 mg Ca per 100 c cm resulted in firm contraction In the seventh experiment clottin was very incomplete with 38 mg Ca per 100 c cm an quite complete with 42 mg Clotting is considered com plete when fluid removed from clot produces no mor fibrin when further calcium is added

Column 4 of table II shows total calcium, which derived from the known calcium added and an assumed figure of 10 mg per 100 c cm for the natural Ca content of serum and of 6 7 mg per 100 c cm for citrated plasm —an average experimental figure Column 6 shows the overall citrate in millimols based on the average figur of 780 mg per 100 c cm for citrated plasma during the first twelve days of storage In view of the fact that the experiments were carried out on pooled samples, the error in assigning average values for calcium and citrate are probably small, and the assumptions allow the establishment of an absolute relation between calcium and citrate This relation is not a simple one, since clotting depends on the presence of ionised calcium In the presence of citrate a small proportion of the calcium remains as a positively charged ion, the rest forms part of a negatively charged citrate-calcium complex (Hastings et al 1934) which is inactive in the clotting of blood The dissociation of calcium citrate into *Ca*++ and the inactive citrate-calcium anion may be derived from the equations of Hastings and his colleagues The situation in plasma and serum, however, is complicated by the presence of proteins which also form complexes with calcium probably similar to those formed by citrate, and which are chiefly responsible for the un-ionised calcium of normal uncitrated plasma and serum McLean and Hastings (1935) give data for calculating ionised calcium in the presence of protein The following approximate equation, derived directly from those of Hastings and his colleagues enables Ca^{++} to be calculated in the presence both of citrate and protein

$$[\text{Total calcium}] - [\mathrm{Ca}^{++}] = \frac{[\mathrm{Ca}]^{++} \times [\text{total citrate}]}{[\mathrm{Ca}^{++}] + \mathrm{K}/(\text{citrate}) \times 10^3} + \frac{[\mathrm{Ca}^{++}] \times [\text{total protein}]}{[\mathrm{Ca}^{++}] + \mathrm{K}/(\text{protein}) \times 10^3}$$

$$\left.\begin{array}{ll} {[\mathrm{Ca}^{++}]} & = \\ {[\text{Total calcium}]} & = \\ {[\text{ ,, citrate}]} & = \\ {[\text{ ,, protein}]} & = \end{array}\right\} \begin{array}{c}\text{concen-}\\ \text{tration}\\ \text{of}\end{array} \left\{\begin{array}{ll}\text{ionised} & \text{calcium}\\ \text{total} & \text{,,}\\ \text{,,} & \text{citrate}\\ \text{,,} & \text{protein}\end{array}\right\} \begin{array}{c}\text{in millimols}\\ \text{per litre}\end{array}$$

K/(citrate) is the dissociation constant of the reversible reaction

$\mathrm{Ca\ citrate}^{-} \rightleftharpoons \mathrm{Ca}^{++} + \mathrm{Citrate}^{=}$ It equals 0 0006

K/(protein) is the dissociation constant for $\mathrm{Ca\ protein} \rightleftharpoons \mathrm{Ca}^{++} + \mathrm{protein}^{=}$ It equals 0 006 The fact that one constant is ten times the other is fortuitous

Protein is calculated from an average figure of 7% for pooled serum and 4 65% for pooled citrated plasma The figure is converted into milli-equivalents per litre by means of the factor 2 43 (Van Slyke et al 1928) and the number of milli-equivalents divided by two, according to McLean and Hastings (1935) gives the value in milli mols The conversion is based on their hypothesis that protein behaves towards calcium as though it were composed of a number of negatively charged divalent ions This hypothesis they support by experimental evidence

Ca^{++} has been calculated from the above equation, simplified by the substitution of millimolar contents for llimolar concentrations this does not introduce preciable inaccuracy The effect of plasma and serum agnesium on calcium has not been considered according to McLean and Hastings (1935) the action of magsium is negatived by the presence of the natural citrate und in small amounts in normal plasma and serum

It will be seen (table II, column 8) that the figure for nised calcium is almost the same in all the plasma-serum ixtures, whether the proportion of serum be high or low is difficult to escape the conclusion that when serum used to clot plasma the action is not due to preformed serum thrombin but to the natural content of serum calcium which becomes available for the plasma in the serum-plasma mixture and which with any calcium otherwise added helps to overcome the anti-coagulating effect of the citrate If the clotting effect of preformed serum thrombin were important it would not be necessary, in serum-rich mixtures, for so much thrombin to be supplied by the plasma: less plasma prothrombin would need to be converted into thrombin and less calcium would have to be added to ensure complete clotting This would result in a fall of Ca-- The absence of such a fall indicates as we have seen, that the clotting effect of preformed serum thrombin is unimportant This is to be expected on general grounds, for while enough thrombin can be formed in one volume of uncitrated plasma to convert the whole into serum, once the conversion is complete so little active thrombin is left, that it now requires five volumes of serum to clot one of plasma

TABLE II—CLOTTING AND IONISED CALCIUM

erum (parts)	Plasma (parts)	Ca added	Total Ca	Total Ca	Citrate	Protein	Ionised calcium
		mg per 100 c.cm		mM.p.l			
5	1	0	9 4	2 35	5 1	8	0 29
4	1	1 5	10 8	2 7	6	7 9	0 3
2	1	6	14 9	3 73	10 1	7 6	0 27
1	1	13 5	21 9	5 48	15 1	7 1	0 29
1	1 5	18	26	6 5	18 2	6 8	0 29
1	2	21	28 8	7 2	20 2	6 6	0 29
0	1	42	48 7	12 2	30 3	5 6	0 36

mM.p l = millimols per litre

In spite of this conclusion however one must not overlook the fact that serum has some effect in clotting plasma other than that due to its calcium content for in the last record of table II where plasma is clotted by calcium alone in the complete absence of serum sufficient calcium must be added to produce a sharp rise in the ionised calcium If a certain minimum of serum is present much less calcium is needed to produce complete clotting and Ca-- falls but further increase in serum is not accompanied by a corresponding decrease in ionised calcium Apart from this obscure qualitative effect, the chief use of serum is to add calcium to citrated plasma and aid clotting without raising the calcium content of the mixture above the physiological level and without decreasing the protein content

Weaker Citrate Solutions as Anticoagulants

Harington and Miles (1939) used 180 c cm of a solution containing 0 85% sodium chloride and 1 05% sodium citrate to prevent the clotting of 360 c cm blood or 0 53 g citrate per 100 c cm blood The M R C recipe at present in use employs 100 c cm 3% citrate for 420 c cm blood or 0 72 g citrate per 100 c cm blood Both preparations are efficient in preventing blood clotting, but while the higher citrate may have a special value in stabilising plasma after filtration through bacterial filter pads, it has a definite disadvantage if the material is to be converted into serum with either calcium or serum or a calcium serum mixture If the straight filtration of plasma were ever abandoned in favour of a conversion to serum before filtration then the following citrate preparation would be suitable 100 c cm of a solution containing 2 22 g sodium citrate, and 0 2 g sodium chloride to 420 c cm blood or 0 53 g sodium citrate to 100 c cm blood The use of such a solution would allow of considerable reductions in the amounts of calcium required to produce complete clotting, as a comparison of tables III and I will show

TABLE III—CALCIUM AND SERUM REQUIRED TO CLOT PLASMA

(Plasma from 420 c cm blood with 100 c cm 2 22% Na citrate and 20 c cm 15% glucose solution)

Serum (parts)	Plasma (parts)	Ca added	Final overall Ca
		mg per 100 c cm	
2	1	5	13 9
1	1	11	19 4
1	1 5	13	21
1	2	17	24 8
0	1	35	41 7

In order to allow a margin of safety the figures in table III are slightly higher than the experimental values, which are shown in table IV and from which the values for ionised calcium are calculated Citrate in this series was estimated directly Duplicates did not agree very well (22 4 and 24 2 mM.), but the error will have no effect on the relative values for Ca--, while the absolute effect will be not more than ± 6%

TABLE IV—CLOTTING AND IONISED CALCIUM

Serum (parts)	Plasma (parts)	Ca added	Total Ca	Total Ca	Citrate	Protein	Ionised Ca
		mg per 100 c.cm		mM p l			
2	1	3	11 9	2 98	7 8	7 6	0 26
1	1	9	17 4	4 35	11 7	7 1	0 28
1	1 5	11	19	4 75	14	6 8	0 27
1	2	14	21 8	5 45	15 5	6 6	0 28
0	1	30	36 7	9 17	23 3	5 6	0 32

It will be seen that the figures for ionised calcium required to produce complete clotting of plasma in this series are as in table II about 0 28 mM p l in all systems except the last in which serum is completely absent and where Ca-- is definitely raised

Clotting by Dialysis

The clotting of plasma by dialysis is at present quite experimental If citrated plasma is dialysed in Cellophane bags against a solution of sodium chloride (0 8%) and calcium chloride it is possible to lower the citrate content of the plasma while the calcium content may be varied at will, according to the amount of calcium chloride added to the saline solution Thus 1 volume of plasma containing 780 mg sodium citrate per 100 c cm will clot when dialysed against 2 75 volumes of saline containing 15 mg calcium while if a plasma with weaker citrate (600 mg per 100 c cm) is used only 2 volumes of saline will be needed The final plasma calcium is about 13 mg per 100 c cm Dialysis is carried out in the cold room After two days, the cellophane bags are hung up at room temperature for a few hours to clot, and then returned to the cold room for clotting to complete itself Dialysis is not continued during the second period in the cold room

Clotting by means of dialysis involves a reduction of sugar potassium, magnesium and other substances in the plasma As the first two are greatly increased in time-expired plasma, a reduction is advantageous Loss of magnesium and bicarbonate could be made good by adding magnesium salts and bicarbonate (or possibly sodium lactate) to the saline though it is doubtful whether these particular compensatory modifications are necessary On the other hand dialysis may well cause a decrease in other crystalloids whose importance is not at present appreciated. Finally, it must be emphasised once again that clotting plasma by dialysis is still experimental It is not certain that consistent asepsis can be maintained during the processing nor is it known if decrease in crystalloids during dialysis impairs the therapeutic value of the preparation

Summary

Citrated plasma may be clotted by serum alone or by calcium salts If serum and calcium are combined clotting may be obtained with an economy of serum and with only a moderate increase in total calcium

Citrated plasma may also be clotted by dialysis against 2 75 volumes of saline containing 15 mg per 100 c cm calcium This method does *not* require serum and the final total calcium is only slightly greater than normal But it does involve the decrease of crystalloids which may conceivably be of physiological importance Moreover the processing of material in an aseptic manner may be difficult At present, clotting of plasma with mixtures of serum and calcium is the method of choice

In the absence of serum, about 0 34 millimol ionised calcium per litre is needed to clot plasma If a small amount of serum is added, only 0 28 millimol ionised calcium per litre is needed, but further increase in serum does not cause a corresponding fall in the ionised calcium needed for complete clotting

FLEXED PLASTER SPICA
FOR FRACTURED FEMORAL NECK

W A COCHRANE, M B EDIN , F R C S E
SURGEON TO THE PRINCESS MARGARET ROSE HOSPITAL, EDINBURGH, AND ASSISTANT SURGEON TO THE ORTHOPÆDIC DEPARTMENT OF THE ROYAL INFIRMARY

THE treatment of fractures of the neck of the femur depends on the age and general condition of the patient, the site and angle of the fracture, and on the presence or absence of impaction, displacement or comminution It is dangerous to confine an old person with a fractured hip to bed, because of the risk of bedsores, pneumonia, and mental and physical deterioration In the days before good reduction and fixation, when fracture of the neck of the femur was regarded as the "unsolved fracture," the case-mortality was 16% (Nix 1916) to 18% (Speed 1916) About forty years ago, Royal Whitman of New York pointed out that fractures of the neck of the femur could be reduced by manipulation and fixed in abduction, extension and medial rotation of the hip, with the expectation that bony union would take place in 50% of the intracapsular fractures This was a great step forward, but even so the mortality of this method has been 12–15% (*Lancet*, Sept 13, 1941, p 316) Lofberg (1924) reports the end-results of the abduction method in 306 cases of fracture of the neck of the femur, 67% of the medial fractures united by bone, and all the basal fractures In the abduction fracture at the subcapital level the fragments are impacted at the outer side Conservative measures may be employed with confidence in obtaining bony union in such cases Adduction fractures may occur at any level The effect of muscle-pull and weight-bearing on this class of case is to drive the fragments past one another, especially if the fracture-shaft angle is small Careful and complete immobilisation of the reduced fracture is essential The position of the fracture line, its inclination, and the presence or absence of comminution are important in prognosis, whatever method of treatment is employed Not only transverse fractures of the neck of the femur are encountered but also spiral, oblique and comminuted fractures Leadbetter (1933) points out that it is as difficult to maintain position in a spiral and comminuted fracture of the neck of the femur as in any other bone Shatara (1941) finds that subcapital and comminuted fractures have been disappointing in their response to internal fixation The nearer the fracture to the head of the bone, the poorer is the blood-supply and the more difficult to maintain reduction

What is known as the fracture-shaft angle may be taken as an accurate index of the thrust and shearing forces to which the fracture is subjected One line of the angle is the axis line of the femoral shaft, and the other follows the fracture-surface on the shaft fragment, as seen in the anteroposterior film of the hip when medial rotational displacement has been corrected In connexion with Pauwel's angle also it has to be b mind that there may be considerable shearing concentrated in the angle shown in the lateral The fracture-shaft angle must be given due value assessing indications for correct treatment, if op is contemplated In a critical review of the results of the operative treatment in 75 fractures treated by closed pinning, Eyre-Brook Pridie (1941) consider that if there is a low fra shaft angle, below 30°, the case requires more Smith-Petersen's triflanged pin alone , either the tion of a bone-graft is required or the case should treated by subtrochanteric sliding osteotomy internal fixation can be applied to most intra fractures, it is not to be recommended in some

Internal fixation (Smith-Petersen et al 1931, 1935, Putti 1940) is the method which has first claim most adduction fractures of the narrow part of the of the femur, and it is often chosen for uncom displaced fractures of the broad part But in spite the good results obtainable in expert hands by this method studies of end-results now beginning to appea make it clear that intracapsular fractures of the neck of the femur still present a difficult problem A commission set up by the American Academy of Orthopædic Surgeons (1941) has analysed the late results of internal fixation in 247 subcapital and transcervical fractures Bony union followed in 169 cases (70 1%), non union in 30% The analysis of 923 cases treated by operation revealed a mortality of 11 6%—a figure very similar to that obtained with the Whitman method Arthritic changes developed in a quarter of the cases in which bony union was obtained In the series of Eyre-Brook and Pridie (1941), bony union occurred in 70% of the intracapsular cases

From a considerable personal experience of nailing intracapsular fractures I find that the majority unite by bone, but I have been disappointed by the commonness of late arthritis Cases of aseptic necrosis have not occurred, probably because the subjects were not young All cases of fracture of the neck of the femur do not live on uninterruptedly well after successful pinning Bony union from conservative treatment is the best obtainable because there are no unfortunate immediate and late complications to be feared In view of the varying circumstances and conditions in which fractures of the hip are treated, conservative methods can be advised with a good deal of confidence on account of the excellent end-results achieved in a high proportion of cases Cases occur in remote parts of the country and in the Outer Islands where expert care by operation is not always readily available If an intracapsular fracture of the neck of the femur is well reduced and held, it has a good chance of uniting by bone If bony union does not take place it is possible to appreciate the fact in time and resort to nailing Actually, half the intracapsular fractures of the femoral neck unite by bone with conservative measures With new facts coming to light, it should be possible to recognise the type of case favourable for obtaining bony union by a conservative method, and the type which will give poor results by operation

It may be objected that while good closed reduction to a hair-line may well be obtained by the appropriate manœuvre, adequate fixation cannot be obtained in a plaster or appliance for intracapsular fractures The reply to this is that in the event of really good reduction —possibly completed by Cotton's (1924) impaction—of an intracapsular fracture, any movement which may take place subsequently at the hip is more likely to occur at the joint than at the fracture

HIP-FLEXION METHOD

Plaster fixation of the reduced fracture in flexion of the hip should help in solving the problem of treatment It offers special advantages in some cases, and even may be the method of choice for a particular case It provides a middle course between internal fixation and the prolonged confinement to bed necessitated by the Whitman extended and abduction position, the Wilkie butterfly splint or the Roger Anderson well-leg traction method for basal or pertrochanteric fractures In impacted fractures of the broad part of the neck of the femur, it may not be advisable to undo the impaction mobilisation in a light, close-fitting plaster spica plied with the hip in flexion and moderate abduction kes it possible for the patient to be lifted out of bed ily, to change her position in bed, and to lie for a little ch day in the prone position These are outstanding vantages If the nurses are asked how they like the ethod, they reply that it is most satisfactory They nd it easy to handle the patient and to look after the crum The patient and household, too express satis- ction It saves the financial drain of a long period in rsing-homes and hospitals for the patients can be nt home in a few days and it is a method within the mpass of the general practitioner who lacks hospital surgical facilities It is peculiarly applicable to barely built subjects to cases of early or reduced ado- scent epiphyseal coxa vara to fractures of the narrow art of the neck of the femur (both varieties) and to basal nd trochanteric fractures after reduction of the dis- laced cases It can also be applied to subtrochanteric racture if the fracture is oblique from the outer side nwards and downwards

The method is referred to in the textbooks but has not been in common use because light close-fitting plasters were not employed when the method was first described. Then plasters were thick heavy and cumbersome applied over thick padding, so that it became no easy matter to lift the patient out of bed, especially if she was stout and heavy But plaster technique has improved much in recent years Fixation in plaster of the reduced or impacted fracture of the femoral neck is the only conservative method, except the Bradford (1922) abduction splint which allows the patient to leave her bed daily and lead a life of comfort and partial independence during the healing stage

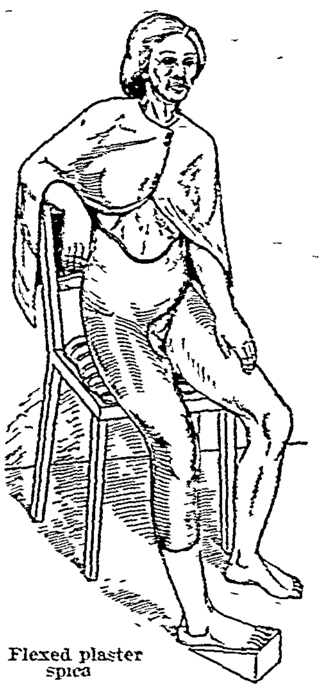
CASE-HISTORY

A woman of 84 had a fracture of the middle of the neck of the femur with considerable displacement An hour before reduction Omnopon, gr ⅓, was given hypodermically. A small dose of procaine hydrochloride (Neocaine) 80 mg, was given intrathecally Stockinet (a thin combination suit or underclothing will do) was drawn on to the limb and trunk The bony prominences of anterior and posterior iliac spines, the head of the fibula and the sacrum and lumbar spines were covered by strips of sticky white felt applied to the stockinet The patient was lifted on to a pelvic rest, the head and shoulders being supported on a padded box. If a pelvic rest is not available, a small upturned basin is used to support the pelvis The sound limb was held by an assistant The reduction of the fracture was performed by the Leadbetter manœuvre.

To apply this method, the assistant supports the unaffected limb in moderate abduction and steadies the pelvis The surgeon faces the injured hip and flexes the knee and hip to a right angle He grasps the ankle with one hand and supports the flexure of the knee on his other forearm By standing on a platform of sufficient height to permit of his holding the limb thus with his body in a half-stooping position, the surgeon overcomes the shortening and practically all the displacement by straightening himself up No additional force is required, a steady lift suffices, keeping the limb in a little lateral rotation while doing so The surgeon now steps off the platform, bringing the hip and knee slowly and steadily into the extended position, at the same time carrying the hip into about 15° medial rotation and then into the abducted position An assistant measures the lengths of the limbs, to see that shortening has been corrected Leadbetter s clinical test for reduction is applied This consists in noting that when the heel of the otherwise unsupported limb is lying upon the palm of the surgeon's open hand, the limb no longer rolls out into lateral rotation.

In this case one felt confident that complete reduction had been obtained and equally confident that, by now gently flexing the hip by about 50° to 60° and reducing the degree of abduction to about 20° from the midline, movement would be more likely to take place at the hip joint than at the site of fracture So it proved The knee was kept flexed by about 25° from the extended position, so that the lower leg acted as a crank handle to maintain position X ray films of the hip were taken in two planes first in the extended and then in the flexed position. It was found that a hair line reduction had been obtained.

A close fitting light and carefully moulded short plaster spica was applied (see figure) Such a plaster need be only about ¼ in thick, save for reinforcement by slabs ⅛ in thick applied to the anterior, posterior and lateral aspects of the hip The foot and ankle have a separate, removable posterior plaster splint made for use in bed It is carried about 1 in. beyond the toes, to keep the weight of the bedclothes off the foot In moulding the plaster spica of the hip the knee and lower third of the thigh are compressed laterally by the palms of the hands Firm anteroposterior compression is used at the mid and upper thigh It is also moulded firmly between the trochanter major and the iliac crest and above the iliac crests In applying the plaster it is important to cover the buttock adequately, this is often done incompletely



Flexed plaster spica

The patient was lifted out of bed two days later, to sit up comfortably in a chair all day This routine was carried out daily Soon after the application of the spica part of the casing was cut out anteriorly over the lower leg and knee to permit of motion in the knee for a short period every day; quadriceps drill was started, and a domette bandage used to hold the knee back again in 25° flexion She was sent home a week after she had first got up The district nurse attended her every morning, and, with the assistance of the patient s daughter, helped her into a chair for the day The patient was soon able to give a good deal of assistance She went on uninterruptedly well, bony union in perfect position took place, and the leg is as good as ever There is full movement in the foot, knee and hip, and the patient is active and well

DISCUSSION

It is worth digressing to note that fractures through the broad part of the neck of the femur and the trochanter major are not unattended by a real risk of fatal pulmonary embolism This risk seems to be lessened if reduction is performed within the first 48 hours after injury, 7–10 days after the fracture is the dangerous period I have notes of 5 cases occurring during a period of 2 years, of proved fatal pulmonary embolism arising at the time of attempted reduction of basal and trochanteric fractures in old female subjects The embolism took place in each case at the time of attempted reduction, 7–10 days after the accident If it is decided to reduce a fracture in this region it should be done forthwith or after a delay of three or four weeks The danger is a real one, and relatives should be warned of it.

It is commonly imagined that the abduction method of treating fractures of the neck of the femur consists only in carrying the limb out into abduction Reduction cannot take place until the shortening has been manually corrected the trochanter and shaft have been lifted forwards and lateral rotation has been corrected, it is then that abduction is carried out The Leadbetter manœuvre and test should be known to all who may have to deal with these injuries

Persistent local tenderness is a diagnostic sign in these cases of fracture of the femoral neck which often occur in stout subjects in whom the classical features of shortening deformity and complete loss of function are absent. The pain is often referred to the thigh and knee and not to the hip itself

Moore (1928) has employed the plaster fixation method routinely and successfully for many years He states that owing to the position of flexion abduction and medial rotation the capsule and muscles of the hip are used advantageously in maintaining reduction, and that flexion puts the gluteus maximus and medius on the stretch, thus forming a strong natural hammock and preventing backward displacement and eversion of the thigh He urges the use of spinal anæsthesia in reduction Campbell (1919) reported the successful use of the method in 3 cases Judet (1921) also reported favourably on it Cannaday (1930) reports that for several years he has advocated and practised the application of a plaster case in a modified Whitman position He calls it the sitting Whitman position

My own experience of the flexion method, though not extensive, has been satisfactory, and I have been favourably impressed by the comfort and well-being of the patients The method can control the reduced fracture effectively, but if there is doubt about this, the other thigh can be included and a cross-bar for lifting incorporated just above the knees It is possible to attempt reduction under morphia alone, but the addition of a local or spinal anæsthetic is preferable

Plaster fixation is the revival of an old method, but with a difference It is applied after accurate reduction, controlled by improved X-ray technique, and relies on the efficiency and lightness of a close-fitting plaster

SUMMARY

Fractures of the neck of the femur are important and common injuries, associated even now with considerable mortality and disablement

Reduction and immobilisation, combined with as much normal activity of the body and limb as possible, are the immediate objectives of treatment

The hip-flexion method with plaster fixation has a part to play in achieving these aims, and in promoting union

FORMERLY HOUSE PHYSICIAN AT THE MIDDLESEX HOSPITAL

Two atypical cases of acute bacterial endocarditis, each possessing distinctive features, have recently come to our notice

CASE 1 —A married woman aged 60 Her past history was given by her husband, an intelligent observer She was quite well until Jan 4, 1941, when she was taken ill in the night and vomited, complaining of severe pain in the left chest and back She remained in bed, and on Jan 6 complained of sudden severe pain in the left foot, which went white, and then became blue as the pain decreased On the evening of Jan 11 the same phenomenon occurred in the right hand On Jan 6 small purpuric spots had appeared in the skin over both patellæ, and on the same day her nose and the surrounding 1½ in of the face had become faintly blue She complained of no pain in the nose until Jan 11 when it had become deeply discoloured (fig 1)

When admitted to hospital on Jan 12 her pulse rate was 124, temperature 96 4° F, respirations 30 The pulse was regular in the left arm, but in the right arm no pulsation was palpable in the radial artery or ante cubital fossa In the left foot, which was cold and blue, pulsation in the dorsalis pedis artery was present and equal to that in the right foot The nose was a deep purple and tender, and the skin around it was discoloured by petechiæ The heart was enlarged towards the axilla, with the apex beat 1 in outside the midclavic line The heart sounds were distant, but both could be hea in all areas, there was a soft blowing systolic murmur at t apex conducted to the axilla Blood-pressure 130/80 mm H The patient was drowsy on admission and gradually becam more so The nose became more deeply purple, and the bluen of the right hand spread slowly up the forearm A blo count on Jan 14 showed red cells 3,000,000 per c mm, wh cells 42,000 (neutrophils 84 8%, lymphocytes 3 1%, mon cytes 4 1%, no eosinophils or basophils, myeloblasts 2 3%, premyelocytes 2 3%, myelocytes 2 7%, metamyelocytes less than 1%), in counting 300 white cells 1 megaloblast, 1 early erythroblast, 2 late erythroblasts and 1 normoblast were seen Polychromasia, punctate basophilia, anisocytosis and poikilocytosis were noted

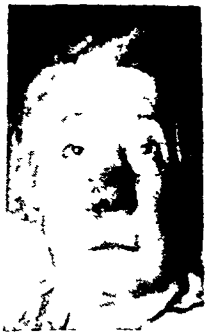

FIG 1—Nasal discoloration due to infarct

By Jan 18 pulsation in the right dorsalis pedis artery was no longer palpable and cyanotic patches had appeared on the left thumb, index and second fingers from deep hæmorrhages Shortly before her death on Jan 23 the skin of her alæ nasi was becoming detached. Throughout her illness she was afebrile

At *autopsy* the findings were those of acute bacterial endocarditis The right pleural cavity contained 140 c cm of blood-stained fluid The heart weighed 13 oz, myocardium flabby and pale Infected clot in tip of right ventricle, attached to the wall of the chordæ tendineæ Tricuspid and mitral valves normal Ulcerating vegetations, in one of which masses of cocci were found, were growing on each cusp of the aortic valve Coronary arteries normal Numerous red infarcts in both lungs Sections showed emboli with clumps of cocci in both kidneys and the spleen

Clinically this seemed to be a case of multiple emboli being thrown off into the blood-stream from the endocardium The blood-count notable for the large number of primitive white cells, was against a diagnosis of endocarditis, and so were the following clinical points she was afebrile throughout, there was little evidence of valvular disease of the heart, the exactly symmetrical cyanosis of the nose was perplexing, in view of the organ's bilateral vascular supply, the occurrence of the pulmonary emboli before the systemic emboli was difficult to explain

In the light of the autopsy findings the absence of fever remains inexplicable There should perhaps have been some indication of the aortic involvement on auscultation, but no murmur was heard in spite of repeated examination with this point in mind The case serves to emphasise the fact that signs in the heart are often lacking in cases of endocarditis The symmetrical cyanosis of the nose had arisen from a single small embolus obstructing the bifurcation of a branch of the external maxillary artery into the lateral nasal and superior labial arteries on one side Thrombosis had occurred subsequently along the superior labial artery to the junction at the bifurcation on the opposite side, thus effectively obstructing the arterial circulation to the area affected The pulmonary infarcts were secondary to systemic emboli blocking branches of the coronary artery, with the resulting infarction of the myocardial tissue they supplied Vegetations formed on the damaged endocardium at the apex of the right ventricle and portions were carried into both lungs The clot formed on the endocardial aspect of one infarct supplied a ready nucleus for the incubation of the causal organism, and the dislodgment of this first thrombus left a suitable starting point for further thrombi to form

CASE 2 —An unmarried woman, aged 21, was sent into hospital as a case of pericardial effusion She was well until Feb 2, 1941, but that evening complained of pain in her back, running up both sides of the vertebral column, into the neck, and over the head She had had vague pains in her abdomen and legs. On Feb 3 she went to bed where she remained until seen by her doctor, who sent her into hospital on Feb 7 At 14 she had been in an orthopædic hospital for a Hibb's spinal grafting operation for Pott's disease She ad not had rheumatic fever or any other diseases relevant to he present illness.

On admission the pulse rate was 112, temperature 101·2° F., espiration 28. She was complaining of pain in the left chest which checked full inspiration. She was very cyanosed about he face and lips; her respirations were laboured, with the alæ nasi working. Tongue coated; pharynx flaked with pus. Pulse regular; apex beat in third interspace, 1½ in. within the midclavicular line. The whole heart appeared to be rotated by the kyphoscoliosis resulting from the spinal caries, so that the apex was displaced upwards and inwards. The first and second sounds were well heard at all areas, but faded in intensity on inspiration. First sound loud and slapping at all areas. A blowing systolic murmur was heard at the apex and conducted to the axilla. At the aortic and pulmonary areas, a diastolic murmur was heard. There was no pericardial friction, or other exocardial sound. The chest was difficult to examine on account of the spinal graft. There was definite dullness on percussion at both bases, with poor movement and greatly diminished air entry at the right base. These findings, with the raised temperature, pulse, and respiratory rates suggested bronchopneumonia. No other abnormal findings.

She was started on a course of sulphapyridine, but this had no effect on her temperature, which fluctuated between 100° F. and 103° F., and the drug was stopped after 12 g. had been given.

Blood count on Feb. 8 showed white cells 4300 (neutrophils 74%). Blood culture in glucose broth medium on Feb. 7 gave a heavy growth of *Staphylococcus aureus*, within 48 hours of incubation. Blood count on Feb. 9 showed an increase in white cells to 11,000 (neutrophils 82%). She slowly deteriorated and died in coma on Feb. 10.

At *autopsy* the lungs contained multiple red infarcts, the parenchyma being congested and œdematous. There was a small effusion in both pleural cavities. The heart was of normal size; musculature of the ventricular walls of average consistence, the right ventricular muscle being definitely thicker than the left. The interventricular septum was deficient in the upper third. Aortic and mitral valves normal. The pulmonary valve consisted of only one cusp, with two rudimentary attempts at division. Lying in the pulmonary arterial wall immediately distal to the valve were two depressions in which lodged two large thrombi (fig. 2). This was evidently the source of the pulmonary infarcts. Minute beaded nodules could be seen along the free margin of the single pulmonary cusp, indicative of an early valvular infection. The pulmonary artery itself was much narrowed in the first inch of its course.

The girl had apparently led a perfectly normal life up to the time of this illness, and had not been at all incapacitated by such a grossly deformed heart, beyond getting somewhat blue in the face when climbing stairs.

In her "Atlas of Congenital Diseases of the Heart," Maud Abbott does not mention any reported case of a single pulmonary-valve cusp, but the condition is referred to as a rarity in pathological works. This case also bears out the teaching that it is uncommon to find bacterial endocarditis affecting the right side of the heart except in the presence of congenital cardiac deformity. We wished to keep the heart intact as a museum specimen so the depressions in which the thrombi had formed were not explored. It is, however, reasonable to suppose that vegetations had developed at the valve bases at the same time as those on the cusps, and that these had led to the formation of the thrombi. The infection was with *Staph. aureus* which is uncommon in bacterial endocarditis. Section of the diseased valve confirmed the presence of endocarditis and of bacteria.

We are indebted to Miss Margaret Williamson for the illustration of the heart, and to Dr. Raymond Greene for the photograph (originally in colour) illustrating the first case.

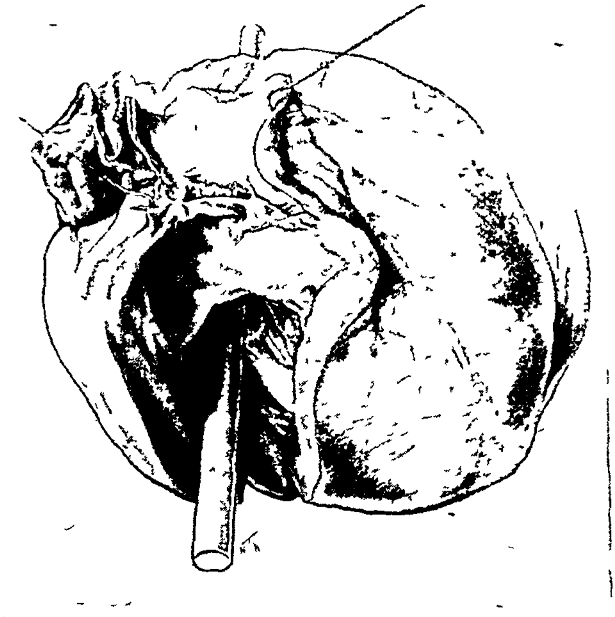

FIG. 2—Heart showing single pulmonary cusp, and depressions behind it containing thrombi.

Medical Societies

ROYAL SOCIETY OF MEDICINE

AT a meeting of the Section of Surgery on Dec. 3, with Mr. E. ROCK CARLING, the president, in the chair, a discussion on

Effects on the Kidney of Trauma to Parts other than the Urinary Tract

was opened by Dr. E. G. L. BYWATERS. Outlining the various types of excretory impairment following trauma, Dr. Bywaters pointed out that the oliguria common after most severe traumata, as well as the albuminuria, hyaline casts and transitory rise in blood-urea concentration sometimes seen, is a functional impairment, due to extrarenal causes, and that renal tubular function itself is seldom impaired. He drew an analogy with the azotæmia of gastro-intestinal hæmorrhage, where one or more of four factors—increased urea formation, decreased filtration pressure, decreased renal blood flow, and decreased renal reserve—may in any given case be involved. After referring to the renal damage following burns and traumatic liver necrosis, he gave an account of crushing injury or compression syndrome, based on 60 cases collected by the M.R.C. through observers throughout the country. This syndrome was first described in Germany during the last war, and it occurred unrecognised after the Messina earthquake in 1909; it was not, however, referred to in Anglo-Saxon writings, despite its occurrence in mining accidents, as McLelland has recently recorded from Canada, and after traumatic injuries to main vessels in civil life. Most cases show no fall of blood-pressure, yet many of these have a reduced blood-volume with hæmoconcentration and compensatory vasoconstriction. This type, only recognised on careful observation, was illustrated by a "crush" case observed by Riddell and Dow without "shock," in which myohæmoglobinuria and temporary azotæmia was associated with loss of a litre of plasma into the tissues and little external sign except some tenseness of the skin over one trochanter. The most important biochemical feature of these cases is the tendency of urinary urea and chloride to approximate to that in the blood, pointing to tubular dysfunction. The associated fall in alkali reserve and rise of serum potassium and phosphate possibly may be partly due to absorption from damaged tissue. Biochemical evidence of recovering tubular function has been seen in a fatal case; death is often sudden and associated with cardiac irregularities not unlike those seen in experimental potassium poisoning. Dr. Bywaters then demonstrated the pathological appearances, particularly emphasising the pigmented casts in the collecting tubules and the necrosis seen in the distal convoluted tubules and in Henle's loop at the boundary zone, with discharge of hyaline casts into the interstitial tissue. This renal change is not specific, for it has been seen after septic abortion, in severe cachexia, in idiopathic paralytic myohæmoglobinuria, and in mismatched transfusion. The pigment excreted in "crush" cases, however, is not hæmoglobin but myohæmoglobin, whose renal clearance thigh He urges the use of spinal anæsthesia in reduction Campbell (1919) reported the successful use of the method in 3 cases Judet (1921) also reported favourably on it Cannaday (1930) reports that for several years he has advocated and practised the application of a plaster case in a modified Whitman position He calls it the sitting Whitman position

My own experience of the flexion method, though not extensive, has been satisfactory, and I have been favourably impressed by the comfort and well-being of the patients The method can control the reduced fracture effectively, but if there is doubt about this, the other thigh can be included and a cross-bar for lifting incorporated just above the knees It is possible to attempt reduction under morphia alone, but the addition of a local or spinal anæsthetic is preferable

Plaster fixation is the revival of an old method, but with a difference It is applied after accurate reduction, controlled by improved X-ray technique, and relies on the efficiency and lightness of a close-fitting plaster

SUMMARY

Fractures of the neck of the femur are important and common injuries associated even now with considerable mortality and disablement

Reduction and immobilisation, combined with as much normal activity of the body and limb as possible, are the immediate objectives of treatment

The hip-flexion method with plaster fixation has a part to play in achieving these aims, and in promoting union

In the light of the autopsy findings the absence of fever remains inexplicable There should perhaps have been some indication of the aortic involvement on auscultation, but no murmur was heard in spite of repeated examination with this point in mind The case serves to emphasise the fact that signs in the heart are often lacking in cases of endocarditis The symmetrical cyanosis of the nose had arisen from a single small embolus obstructing the bifurcation of a branch of the external maxillary artery into the lateral nasal and superior labial arteries on one side Thrombosis had occurred subsequently along the superior labial artery to the junction at the bifurcation on the opposite side, thus effectively obstructing the arterial circulation to the area affected The pulmonary infarcts were secondary to systemic emboli blocking branches of the coronary artery, with the resulting infarction of the myocardial tissue they supplied Vegetations formed on the damaged endocardium at the apex of the right ventricle and portions were carried into both lungs The clot formed on the endocardial aspect of one infarct supplied a ready nucleus for the incubation of the causal organism, and the dislodgment of this first thrombus left a suitable starting point for further thrombi to form

CASE 2—An unmarried woman, aged 21, was sent into hospital as a case of pericardial effusion She was well until Feb 2, 1941, but that evening complained of pain in her back, running up both sides of the vertebral column, into the neck, and over the head She had had vague pains in her abdomen and legs. On Feb 3 she went to bed where she remained until seen by her doctor, who sent her into hospital on Feb 7 At 14 she had been in an orthopædic hospital for a Hibb's spinal grafting operation for Pott's disease She

Major DANIEL MACNEE, Mr J. C. F. LLOYD WILLIAMSON (in conjunction with Dr J. M. JAMES) and Mr W. H. GRAHAM in turn described cases they had had under their care in each of which after a traffic accident with traumatic rupture of the main leg arteries the patient had survived the immediate shock, and that due to subsequent surgical treatment by means of massive transfusions, only to die several days later in uræmia. In the kidney changes very similar to those of crushing injury were found, although in none of the four cases had compression lasted longer than a few minutes. It was mentioned in the discussion on these cases that the pigment of the urine had not yet been identified.

Mr RUSCOE CLARKE presented a case of minor renal disturbance discovered by careful biochemical study in a patient with a major limb injury from an automobile accident. An initial period of oliguria preceded amputation in spite of normal blood-pressure. After amputation the urinary output and urea concentration rose in spite of a fall in blood-pressure. Further specimens of concentrated urine contained numerous hyaline casts. Recovery was uneventful without further sign of renal involvement. The disturbance was presumably pre-renal, associated with incipient shock. The case illustrates the type of minor renal dysfunction following trauma which may easily be overlooked.

Mr GUY BLACKBURN bore witness to the value of sodium sulphate and alkali, urging the importance of correcting the acidosis seen in these patients; he castigated those who have called this the "continuous interference syndrome" and thought that the policy of healthy neglect is mischievous. Anuria may be due to sulphapyridine, but is in some cases not a failure to secrete but an inability to pass urine; he advocated instead of the daily catheterisations sometimes necessary the institution of tidal drainage.

In England Now

A Running Commentary by Peripatetic Correspondents

Two of the first babies I delivered after I had settled in this practice left school this summer. Mary is going to my old hospital to nurse, Joan has started at the university. I am fond of them both, but Mary's decision brought back vividly my time in the private wards when for four weeks I lay on my back and a number of probationers, staff nurses and two sisters came at odd times to minister to me physically or stimulate my inquiries. So competently did they dispel my aches and pains by the way they dressed my wounds or rolled me about that I decided there and then that I would value my own surgical skill less and attribute a good deal more to the nurses. I even wished that every surgeon who is rude and cantankerous to his staff should fall into the power of those he fumed at, so that he might appreciate their skill.

But my time as a patient left me with other queries. What is it that makes some nurses good and others bad? Is finance alone (as some seem to think) the key to attracting better probationers? From my experience I am clear that the nursing school counts. This is not mere pride in my alma mater. Those who controlled me so quietly were not merely efficient automata, they were also intrigued with their duties. Sisters, tutors and ward sisters had given them an interest in their patients not merely born of necessity. In other words, they were motherly and all-expectant, but they brought what must be called intellectual stimulus to their job as well. The sentimentally sympathetic one bored me; the best educated one alarmed me. The former seemed to be treating me rather as I suspect she treated her dolls till the age of 12. The latter had ideals and ideas, but she didn't carry out the heroic and her plans for the future she had to admit were absurd. It all sounds very well on paper, and she might convince audiences but not colleagues. The first hadn't grown up; the second was in nursing from mistaken motives. The one had little use for intellect, the other had hardly any conception of "understanding."

As one reads the reports of those who want to attract more women into the nursing profession, one wonders whether salaries loom as large as they are said to and how far the tales that "nursing is a glorious profession" stir the adolescent. As far as discreet inquiries could go, none of my mentors had private means but the glamour motive of Florence Nightingale had loomed fairly large. Are the words "glorious profession" really representative? Just as the university graduate speaks glowingly of his three years as a student, so the nurse waxes enthusiastic over the life in hospital. Does finance count much? Big salaries may attract potential nurses into other posts. I doubt if poor pay discourages many enthusiastic schoolgirls. Their idealised nurse may be a creature "that never was on sea or land," and the new probationer's first contact with an unimaginative ward sister may set the tone for all her future musings on her profession. I am concerned not so much for finance, nor for the junior, but for the equipment of the trained nurse who as a sister in her own or another hospital will influence so greatly the probationers she trains.

What is it that we ask from our nursing students? Physical labour, rigid compliance with a certain tradition, keen observation, a willingness to suffer criticism, thanklessness. We offer the satisfaction of well-earned fatigue, gratitude from patients and a keen development of the five senses that converts the senior sister into an acute observer (more acute than any man doctor usually is), with friendship and a deep-seated realisation of the maternal instinct. When Mary's friend Joan goes to the university, what is she offered over and above learning? Some insight into scientific methods and a closer understanding of great minds, the ability to connect more and more of the jigsaw of experience and to see where economics influences politics, geology directs trade, human incompatabilities affect national aspirations. Most important of all, she discusses with her colleagues, not the crushes of schoolgirls, but the interconnexion of all she studies with the world she learns of in the debating hall or from the social and cultural difference of students drawn from divergent schools.

It is easy to assume that Joan's experience at the university is better in quality than Mary's in hospital. We hear a good deal of "nurses only interested in young men," sometimes derogatory remarks of a nurse's intellectual attainments. If Mary will in four years be a skilled nurse with an eye on the marriage market, and Joan a first-class private secretary with an eye on the money market, can we say that one will represent a higher type than the other? Even suppose Joan becomes a blue stocking, will she be any better or worse than Mary? But I do admit that Mary might have more cultural interests and Joan have more real experience of human frailties. Joan's deficiencies were thought to be made good in the old days if she came and "slummed" for six weeks. I am not clear that anyone helps to broaden the cultural experience of the Marys. Nurses' libraries are improving, so are the periodicals in them—but free theatre tickets usually come for the worst and not the best plays (are there ever tickets for concerts?). Mary says she is too tired to think of much beyond nursing; Joan believes that by midnight discussions she comes to know about "life." At present the culturally interested nurse is as rare as the effectively useful blue stocking, and matrons and dons might well remember it. The nurse can chatter and gossip, the women students build new Utopias of the imagination. The latter will not necessarily make good teachers or good social workers, any more than the former can contribute to their convalescing patients' interests or their juniors' enjoyment of art (in its widest sense).

The don is a person of authority in her own right. Is the sister? I am inclined to believe that in general she is not. Exceptions there certainly are, but I can't help feeling that what prevents Joan being a nurse (and her mother was a good one) is that she senses that a university career will lead on to something more creative than Mary's career. Mary will ultimately be responsible to a doctor. This is not the freedom towards which Joan is attracted. Nursing is a pseudo-profession remaining the handmaid of the medical profession. It attracts, therefore, not only those who are delighted in its scope but those who shelter under its wings. We know the latter type of doctor. Our view of the nurse may need altering—our attitude to her certainly does.

* * *

He is registered as a rabbit-trapper but might with equal truth be described as a game keeper or a poacher or a combination of all three; a little lean gnome-like is 25 times as great accounting for the lack of plasma pigment The myohæmoglobin comes with other autolytic products from muscle Microscopically there are three types of muscle necrosis—first that due to direct pressure ischæmia where the line bounding the necrotic zone corresponds with that in the skin secondly that probably due to rise of intrafascial tension, where the whole muscle is necrotic irrespective of skin areas , and thirdly where there is necrosis of isolated fibres only The last may be due either to vasospasm, illustrated by a case with perivascular hæmatoma, lack of limb swelling and little if any hæmoconcentration, or to traumatic arterial rupture with limb ischæmia, illustrated by a case seen with Mr W H Graham, following a traffic accident without prolonged compression In a given case any or all of these varieties may be present Apart from the importance of muscle ischæmia, pathogenesis still remained as obscure as that of the anuria of mismatched transfusion, but experiments on dogs by Professor Winton and on rabbits at the London Postgraduate Medical School indicate that there are two factors necessary one producing tubular damage and the other, possibly, obstruction Prognosis is difficult depending on the extent of injury, the rise of blood-urea, and the establishment of a diuresis A third of the cases have recovered Improvement here Dr Bywaters suggested will depend on thinking of renal failure immediately after, or even before, admission, instead of about the fourth day, and protection with alkalis and adequate diuretics before treatment of the shock and the local ischæmia He concluded by emphasising the present ignorance, particularly of the early stages, and pleaded for earlier and more detailed observations

Mr **R H R Belsey** discussed the surgical treatment of the local lesion in relation to the more general changes, and urged the extreme need for detailed observations recorded at the onset of injury and treatment fully investigated cases are still too few for treatment to be other than speculative He cited the changes observed in the crushed limb—œdema with muscle pallor, and necrosis, sometimes corresponding to the areas of direct pressure , an increase of tension within the fascial compartments of the limb , peripheral arterial pulsation sometimes absent when the case is first seen, or an initially weak pulse becoming progressively obliterated Sometimes, however, the pulse is normal, and in one case was stronger than in the uninjured limb At autopsy there is rarely evidence of thrombosis or gross damage to the main arteries of the limb, although in a few instances rupture of a major vessel has been found Intense arterial spasm, demonstrated at operation, seems to be a common cause of the ischæmia Loss of nerve function has been recorded in the majority of cases, probably due to ischæmia rather than to direct pressure, but this usually lasts only 6–12 weeks The skin shows erythema and later blebs, but as a rule evidence of gross trauma is slight From these observations he deduced that the muscle necrosis is ischæmic in origin, due probably to traumatic arterial spasm and possibly to direct pressure also , that with restoration of the blood-supply to the limb there occurs a flooding of the circulation with a hypothetical toxin, and passage of plasma from the blood into the damaged tissues of the limb, resulting perhaps in an increase in subfascial tension Mr Belsey then put four queries, answers to which are necessary to plan rational treatment How long a period of ischæmia is needed to produce necrosis ? He has recently seen a case trapped for 45 min only, although reflex vascular spasm may have been present for longer Is "toxin" production continued after restoration of limb circulation ? At what stage does renal damage take place ? Is muscle necrosis the sole cause of the renal damage ? Searching for collateral evidence, he has found no mention of renal damage in cases of Volkmann's contracture or in the case-records of all patients with limb fracture admitted to a general hospital during the last ten years (although this will not surprise anyone who has ever attempted to elicit vital information from hospital case-notes) Allen's experimental work on refrigeration in ligated limbs may throw some further light on treatment It is difficult to assess the effect of surgical treatment especially when many forms of therapy have to be used concurrently He asked for detailed and accurate observation of all cases and deprecated the tendency to record only cases that recover and to suppress the failures Operative treatment has been little employed as yet probably [illegible] thought quite rightly Primary amputation has been performed in three cases, two of which were fatal and recovered Decompression of the limb by incision the deep fascia has been done in seven cases, of which only three have been recorded , three died and [illegible] survived Decapsulation of the kidneys has been performed in one case with established renal failure, but the patient died Two distinct problems emerge—to save the patient's life, and to save his limb The two aims may be mutually antagonistic in that restoration of the circulation to the crushed limb may lead to a sudden flooding of the body with toxin Mr Belsey then briefly described five cases admitted to St Thomas's Hospital Sector One case with both legs crushed was given "rest and quiet" only until the fifth day, when muscle decompression was performed , she died next day Another with a crushed arm, was also decompressed, and recovered satisfactorily A fourth case will delight the non-interventionists for despite extensive damage and a blood-urea of 460 mg per 100 c cm the patient recovered The most recent case was crushed for 45 min only and showed multiple fractures, myohæmoglobinuria and typical post-mortem findings No evidence has yet been published that surgical treatment has played any part in saving life, and the picture is still too confused for any conclusions on treatment He pleaded for more objective observation and less speculation on treatment

Dr **John McMichael** reviewed the present ideas on treatment Since there is strong clinical and experimental evidence of the importance of autolytic products from muscle in the genesis of renal failure, a rational approach would be to ensure a good flow of urine by warm drinks before release Since these hypothetical noxious substances are only absorbed after re-establishment of the circulation to the leg a tourniquet may be valuable until such a protective diuresis has been established Further slowing of autolysis can be achieved by surrounding the limb with ice which by slowing metabolism will also avert incipient gangrene Sodium citrate and bicarbonate given in adequate dosage will combat the invariable acidosis and may thereby minimise renal damage It may also prevent pigment precipitation Other diuretics have been tried but there is little evidence to favour one more than another

Mr **David Patey** remarked that, as far as surgical experience in this country is concerned this is an entirely new problem He objected to the current use of the phrase "crushing injury" because, in the cases he has seen, there has been no crush in the surgical sense he prefers the term "compression syndrome" The policy of healthy neglect he thought dangerous, and cited a case to support this belief , only by continued observation in the early stage can serious cases be distinguished from trivial ones He then propounded the theory on which was based the treatment used in the two cases published in The Lancet (1941, 1, 780)—that renal damage may be due, not to the passage of substances from muscle to blood but the reverse , since those initial attempts to restore fluid from the limb back into the general circulation he has had no further cases

Mr **V H Riddell** said that early protection of the crush case implies early recognition This can only be achieved by a thorough examination of every case, for in some there is no symptom and only the slightest external sign, such as a transient erythema, to mark a deeper lesion which will later produce renal damage He directed attention to the oliguria seen after other types of shock, including that of surgical trauma the occasional presence of albuminuria red cells and casts in the urine of air-raid casualties which has recently been recorded by Grant and his co-workers Mr Riddell is now making a routine study of all urine passed after severe operative trauma

Prof **J Shaw Dunn** spoke on the pathology of the condition, emphasising the localisation of the necrosis to that part of the nephron used for concentration and acidification He pointed out the similarity to the tubular necrosis evidenced in animals by phosphate and uric acid, and agreed with the treatment proposed by the previous speakers

Mr **R H O B Robinson** asked for information on the value of oxygen therapy and sodium sulphate

THE LANCET

LONDON SATURDAY, DECEMBER 13, 1941

QUARANTINE AND MAN POWER

THE Post Office with its 260,000 workers, is the argest employer of labour in the country Its well-rganised medical branch is as qualified to comment n the health of the adult workers as is the school nedical service on the health of the child In this ssue Dr W L SCOTT records impressive figures vindicating the policy of the Post Office in allowing healthy contacts of infectious diseases to remain at work There is nothing new in the procedure whether applied to school children or adult workers, nor is rigid, indiscriminate quarantine for contacts in hospital wards practised today by experienced administrators But, though the Post Office has been employing this policy with conspicuous success for over 30 years, there are still many industrial concerns units of the fighting and other services, and educational authorities which insist on exclusion of healthy contacts from work or school, many hospital beds are temporarily lost and many patients unnecessarily detained because of the imposition of rigid quarantine The cost to the country must be enormous and the time is opportune to review the position

Quarantine, as applied to persons, is the limitation of the freedom of contacts to mix with others until it is certain they have not contracted the disease to which they have been exposed In its most rigid application contacts are segregated for the longest usual incubation period of the disease, and it is worth remembering that some of the mildest infections have the longest incubation periods A modified procedure consists in excluding contacts from school or work without, be it noted, controlling their movement or company during their enforced absence A serious criticism of this method is that school-children, compelled to remain at home, play with their younger siblings of pre-school age who are much more susceptible than children at school Instead of adopting either of these measures, we may allow the contact to remain at work or school provided he is kept under observation The first examination of the contact, preferably made by the medical practitioner in attendance on the patient, serves to detect missed and abortive cases and chronic carriers The Post Office require their medical officer to carry out such an examination in the case of contacts of diphtheria and scarlet fever Subsequent daily observation during the incubation period aims at detecting the earliest symptoms of the disease In the case of school children it is conveniently left to the school teacher or school nurse, if a doctor is not in daily attendance Adults can report the appearance of symptoms and daily observation is not necessary except in special circumstances Boys and girls in the Post Office are kept under observation by their supervising officers

Any procedure which experience shows to be efficient for the control of infectious diseases among school children, with their greater susceptibility and more frequent exposures, should be adequate for the more immune adult It is therefore pertinent to note that in the official code[1] quarantine of contacts is recommended for one disease only—smallpox (To this exception the Post Office add plague typhus and cholera—diseases omitted from the "no quarantine" code because of their rarity) This policy has been extensively adopted in public and county schools Medical officers of health[2] and school medical officers who have used the method rarely if ever have recourse to "school exclusion" and its more extensive application "school closure" It could therefore be anticipated that results among adults would be even more favourable SCOTT's paper confirms this expectation and is of particular value because statistics bearing on this subject are scanty A follow-up over 10 years showed that of 17,844 contacts of scarlet fever, 1 in 251 (0 39%) subsequently developed the disease This figure fell to 1 in 431 (0 22%) when the very modified quarantine was abolished Corresponding figures[3] for other diseases during the same period were —

	No of contacts	*Subsequently developed the disease*
Diphtheria	7,000	1 in 774 (0 13%)
Measles	17,000+	1 in 670 (0 15%)
Chickenpox	7,000	1 in 218 (0 46%)
Mumps	3,000+	1 in 101 (1%)

Interesting as these figures are as evidence of the slight danger to adult contacts, they are not so important as the number of employees who contracted the disease from contacts, for it is to avoid such spread that quarantine is imposed SCOTT[4] in an earlier paper showed that there was no recorded case of a healthy contact transmitting any of the infectious diseases scheduled by the Post Office This conforms with the modern view that the dangerous disseminators of infectious diseases are chronic carriers, missed and abortive cases, by comparison the healthy contact plays an insignificant part In hospital practice there is wide variation in the use which is made of this and other modern knowledge in the management of contacts There are still many hospital authorities which, on the appearance of a single case of infectious disease, impose rigid quarantine without regard to the seriousness and infectivity of the disease, the age of the contact or his state of immunity Consideration of these factors would permit the release of a high percentage of hospital contacts It must, however, be admitted that advice sufficiently definite to be of value to those without special knowledge of infectious diseases is extremely scarce in medical literature

In a country at total war the importance of SCOTT's paper is that it provides convincing evidence of the enormous loss of healthy man-power for which the old method of quarantine is responsible When modified quarantine for contacts of scarlet fever was the Post Office rule, it resulted in a loss of one working day for each contact, and a total annual loss of 5 2 man-years Had the usual quarantine period of 7 days been imposed, the loss would have been equivalent to about 35 man-years per annum Loss of working time is today the vital concern not only of the individual worker or employer but of the nation Let us offer the MINISTER of LABOUR a present next year of 35 man-years of labour for every quarter of a million creature with a brown wrinkled face looking more than his 45 years Before and during the last war he was a serving soldier During the troubles in Ireland he was taken prisoner by Sinn Feiners and told every night for a week that he was to be executed next morning Such things try a man so he knocked the sentry out with a candlestick and made a dash for it, escaping with nothing worse than a deflected septum He has been a great runner in his time at all distances up to a mile He even won an inter-Services cross-country race when he had been made so tight beforehand by his admirers that he had to stop and vomit at intervals during the contest Not so long ago he and his two growing sons, who have inherited his fleetness, shared all the prizes at a small athletic meeting He has also tried his hand as a jockey and played soccer and boxed for the Army As a gamekeeper he has had many a heroic encounter with poachers and diddekis (as he calls gipsies) in which, if he is to be believed, he always came off best though not necessarily unscathed He owns three scruffy little bitches, two spaniels and an elderly fox-terrier They all look hungry but are happy, obedient and obviously devoted to him To see him handle ferrets and fitches is a lesson in deftness, if they won't go down a hole he kicks their noses gently or flicks them in with his cap, nor do they protest when picked up and carried by their tails With pride he described how the old terrier bitch had fought two foxes and two badgers in an earth for 36 hours on end and then had to be dragged off In some ways he himself resembles a terrier especially when he has his ear to the ground over a "burry" Very handy with a shotgun he is and kills 8000 rabbits a year mostly by shooting He claims to be the only man in England to have been shot at by a rabbit It seems that one day he laid his loaded gun down in a ditch while he went to pick up a ferret Simultaneously a bolted rabbit jumped out on to the triggers and fired the gun, but the rabbit missed and did not stay to give him the other barrel Uncivilised you might call him, but undoubtedly a happy and well-adjusted person He has a very nice set of teeth but only wears them on ceremonial occasions

Reviews of Books

Principles and Practice of Chromatography

L ZECHMEISTER, California Institute of Technology, and L CHOLNOKY, lecturer at the chemical institute, University of Pecs, Hungary London Chapman and Hall Pp 362 25*s*

CHROMATOGRAPHY is based on the fact that different substances in the same solution, when brought into contact with an adsorbing substance, are adsorbed to different degrees The technique was devised and developed by the Russian botanist Tswett in the first decade of this century, but only in the last ten years has it become popular The method is to run the solution slowly through a tube packed with adsorbent, when the substances are adsorbed, not evenly but in separate rings, forming a "chromatogram" This is "developed" by passing pure solvent through the column, when the rings of adsorbed substance travel farther down and move wider apart The different substances are then recovered separately from the adsorbent, in one of two ways The column may be removed from the tube, cut up so as to separate the rings or groups of rings, and the adsorbed substances eluted by suitable solvents from each portion of adsorbent alternatively, the adsorbent is left in situ, and the different substances eluted separately by different solvents, or skilful use of a single solvent The method has great scope Aqueous or organic solvents may be used There is a wide range of adsorbents—alumina lime and sugar being common ones As to the adsorbable substances, it is naturally easiest to work with those which are brightly coloured but methods have been developed for the chromatography of colourless compounds Thus a pigment may be added which is adsorbed to the same degree as the colourless substance, or the latter may be converted into a coloured derivative, or the chromatogram may become visible in ultraviolet light Chromatography is widely used for the separation of mixtures, for testing the homogeneity of a substance or the identity of two substances, or for the concentration of a substance occurring naturally in great dilution Biochemists employ it to isolate vitamins and hormones from their natural sources and to separate carotenoids from serum, pharmacists, for the assay of alkaloids in tinctures, and of vitamins A and D in fish oils, or for the detection of added dyestuffs in food and wines

Professor Zechmeister and Dr Cholnoky have made wide and significant contributions to the subject Mr A L Bacharach and Mr F A Robinson are to be congratulated on a fine translation, and they have included some valuable hints on obtaining suitable adsorbents in England It is a pity that the excellent photographs could not be in colour

Common Skin Diseases

(6th ed) A C ROXBURGH, M D Camb, F R C P London H K Lewis and Co Pp 436 16*s*

THIS medical best-seller has been brought up to date and sections on thorium X and dermatomyositis have been added The section on the treatment of scabies has been revised and it is noteworthy that, while describing more modern methods in detail, the author still adheres to the view that sulphur ointment properly applied will always cure scabies He describes two clinical types of impetigo, and over the vexed question of whether it is streptococcal or staphylococcal in origin he remains moderate No stress is laid on the differential diagnosis between impetigo and impetiginised seborrhœic dermatitis of the face, which is important from the point of view of treatment The book finishes with a short section on the avitaminoses which suggests, quite accurately, that our knowledge of the relationship between vitamin deficiencies and diseases of the skin is still rather vague

Dental Materia Medica, Pharmacology and Therapeutics

(2nd ed) WALTER J DILLING, M B Aberd, and SAMUEL HALLAM, L D S R C S London Cassell and Co Pp 348 13*s* 6*d*

A SECOND edition of this excellent handbook is welcome A book on pharmacology must be kept up to date to be of practical value, and the authors have spared no pains in revision The new accounts of the sulphanilamides, antiseptic dyes, buffered local anæsthetics and of the analeptics are well done, and the section on vitamins, which incorporates the recent advance in knowledge, particularly regarding P, E and K, is helpful The work on premedication is clear and concise, though not all will agree that it is wise for a dentist to use many of the drugs except in collaboration with the patient's doctor Professor Dilling points out that unusual symptoms in procaine hydrochloride injection are generally due to the rapid absorption of adrenaline which procaine promotes, though to a less extent than cocaine For years many dentists have recognised this from clinical evidence, but the hypodermic preparations still contain adrenaline The first-rate therapeutic notes in this book make it a real clinical guide

Cardiac Classics

F A WILLIUS, M D, chief of the section of cardiology, Mayo Clinic, and T E KEYS, M A, reference librarian at the Clinic, London Henry Kimpton Pp 858 50*s*

IN the attempt to keep pace with present developments the original writings of the historical giants of medicine are seldom read except by librarians and bookworms But many classical papers teach lessons in observation and lucid expression from which any member of the profession may profit We warmly welcome, therefore, this collection of 52 papers by 51 authors whose work in the past three centuries has done most to further knowledge of the circulation In the first paper—Harvey's "De Motu Cordis," which is reproduced in full—the superbly simple experiment to demonstrate the direction of blood flow in the veins of the arm, which reversed previous conceptions, is a perfect example of observation and description The last paper, by J B Herrick who is still with us, contains the first clinical picture of coronary thrombosis Other contemporaries "must remain patient until some future compilers honor them" A short biography of each author is appended, 27 of the 51 are British

This medical best-seller has been brought up to date and sections on thorium X and dermatomyositis have been added The section on the treatment of scabies has been revised and it is noteworthy that, while describing more modern methods in detail, the author still adheres to the view that sulphur ointment properly applied will always cure scabies He describes two clinical types of impetigo, and over the vexed question of whether it is streptococcal or staphylococcal in origin he remains moderate No stress is laid on the differential diagnosis between impetigo and impetiginised seborrhoeic dermatitis of the face, which is important from the point of view of treatment The book finishes with a short section on the avitaminoses which suggests, quite accurately, that our knowledge of the relationship between vitamin deficiencies and diseases of the skin is still rather vague

Dental Materia Medica, Pharmacology and Therapeutics

(2nd ed) Walter J Dilling, M B Aberd, and Samuel Hallam, L D S R C S London Cassell and Co Pp 348 13*s* 6*d*

A second edition of this excellent handbook is welcome A book on pharmacology must be kept up to date to be of practical value, and the authors have spared no pains in revision The new accounts of the sulphanilamides, antiseptic dyes, buffered local anæsthetics and of the analeptics are well done and the section on vitamins, which incorporates the recent advance in knowledge, particularly regarding P, E and K, is helpful The work on premedication is clear and concise, though not all will agree that it is wise for a dentist to use many of the drugs except in collaboration with the patient's doctor Professor Dilling points out that unusual symptoms in procaine hydrochloride injection are generally due to the rapid absorption of adrenaline which procaine promotes, though to a less extent than cocaine For years many dentists have recognised this from clinical evidence but the hypodermic preparations still contain adrenaline The first-rate therapeutic notes in this book make it a real clinical guide

Cardiac Classics

F A Willius, M D, chief of the section of cardiology, Mayo Clinic, and T E Keys, M A, reference librarian at the Clinic, London Henry Kimpton Pp 858 50*s*

In the attempt to keep pace with present developments the original writings of the historical giants of medicine are seldom read except by librarians and bookworms But many classical papers teach lessons in observation and lucid expression from which any member of the profession may profit We warmly welcome, therefore, this collection of 52 papers by 51 authors whose work in the past three centuries has done most to further knowledge of the circulation In the first paper—Harvey's " De Motu Cordis," which is reproduced in full—the superbly simple experiment to demonstrate the direction of blood flow in the veins of the arm, which reversed previous conceptions, is a perfect example of observation and description The last paper, by J B Herrick who is still with us, contains the first clinical picture of coronary thrombosis Other contemporaries " must remain patient until some future compilers honor them " A short biography of each author is appended, 27 of the 51 are British it seems to have helped to combat shock and it certainly stopped local pain and got rid of smell from the stumps. It is noteworthy that pieces of skin which had not been included in the ice were gangrenous whereas equally detached pieces which had been cooled were well preserved. These results deserve to be considered in relation to severely damaged limbs in both war and civil injuries. Cooling might play a useful part when the number of the casualties outstrips the capacity of the operating teams, and lives are lost because patients cannot be brought to the table within the optimum period. Of theoretical interest is its possible application to crush injuries, mentioned in the discussion at the R.S.M. reported on another page. The chance of a crushed limb surviving appears to be greater if it is cooled, and the onset of signs of nerve injury in cooled limbs is said to be greatly delayed. ALLEN has shown experimentally that it is possible to retain a tourniquet for a long time on a cooled limb when the presence of injected poisons, such as strychnine, make its removal unsafe except for very short periods; thus if so-called crush syndrome is due to circulation of poisons elaborated in the crushed tissues the use of cooling and of a tourniquet with graded periods of release might prove effective treatment. Amputation for crush syndrome can only be justified to save life, for in many cases the survival of the crushed tissues is not in doubt. Much of ALLEN's writing is speculative, and not all his opinions carry conviction; but he has attempted to test his ideas by experiment and his findings certainly merit further study.

VACCINATION AGAINST INFLUENZA

VACCINES made from living or inactivated influenza A virus are effective in immunising laboratory animals, and we know a good deal about the conditions governing success. Attempts to apply this knowledge to the protection of human beings have yielded no conclusive results, mainly because an influenza outbreak has not hitherto been obliging enough to attack a vaccinated community at an appropriate interval after vaccination. Now at last comes news from the United States which provides us with real information on this question. HORSFALL, LENNETTE and RICKARD[1] have lately described an influenza A virus vaccine made by growing the virus in developing eggs and then inactivating it with formaldehyde. This vaccine was given[2] to nearly 8000 people in 15 institutions in the Southern States, about 40% of each institution being inoculated and the rest serving as controls. HORSFALL and his co-workers were lucky in that an outbreak of influenza, mainly due to A virus, occurred in 10 of these institutions about four months later. In 4 of these they used a batch of vaccine which proved in laboratory tests to be of much poorer quality than the others; the people who received vaccine from this batch showed little if any evidence of protection. Among 3455 people receiving other batches 193 cases of "clinical" influenza occurred. Serological studies on 137 of these persons indicated that 81 of them had presumably suffered from influenza A, the incidence being 3.3%; this contrasts with a corresponding figure of 6.6% for the control group. Thus the vaccine of which a single subcutaneous dose of 1 c.cm. had been given appeared to halve the incidence of influenza A. Mixed with the influenza A cases were smaller numbers of cases of "clinical influenza" not due to virus A; the incidence of such cases was virtually unaffected by the vaccination. If all the cases of "clinical influenza" of whatever cause are lumped together, the reduction of incidence by vaccination seems to have been from 8.3% to 5.6%.

These results are particularly interesting if read in conjunction with a paper by the same authors[3] on the correlation between neutralising antibodies and susceptibility to influenza. Almost all adults have some antibodies against influenza A virus in their sera and it has been known for some years that vaccination with formolised virus will increase the titre of such antibodies. Whether or not this is a worthy aim obviously depends on whether possession of potent antibodies affords significant protection against the disease. The American workers examined 1321 normal people serologically and classified them into groups having different antibody levels; they then observed the influenza attack-rate in the different groups in the following months. It appeared that a high antibody titre against A virus renders you less liable to attack by that virus, but not enormously so. If you are in the most favourable group, which contains only 2.7% of the community, your chances of escaping flu are only five times better than the average, while however poor your antibodies you are only about twice as susceptible to flu as the average. It thus seems that antibody level is only one factor determining resistance to influenza A; doubtless the size of the dose of virus reaching your respiratory tract is another. From the known effects of vaccination on antibody level, and the relationship between antibody level and immunity, it is possible to predict what reduction in incidence should be achieved by vaccination. Such calculation does not encourage hope that use of the existing vaccine will produce more than a 30% reduction in persons exposed four months after vaccination. After a shorter interval protection should be rather better and after longer periods rather worse. Actually the American trials showed a 50% reduction, somewhat better than that expected. It may be hoped that improved vaccines will give bigger antibody rises and better protection; but since first-class antibodies only promise the individual moderate protection, we cannot hope that progress along these lines will ever guarantee him immunity. An epidemiological outlook is perhaps more hopeful. Future investigators may look aside from the individual and consider the relation between the average antibody level of the community and the likelihood of an epidemic. If epidemics do not occur when this level is high, vaccination of all or nearly all of a closed community might produce excellent results, though the benefit would be difficult to prove conclusively.

One aspect of Horsfall and Lennette's vaccine cannot yet be pronounced on. Following up some remarkable and at present inexplicable findings in ferrets, they made their vaccine by infecting eggs simultaneously with the viruses of influenza A and workers who, at present, are excluded from work if they become contacts of scarlet fever , and then offer to throw in all the man-years which can be saved among contacts of other infectious diseases Experience in the Post Office shows that it can be done Medical advisers to all government departments, local authorities and industrial concerns should forthwith review their instructions or advice on the management of contacts, and thereby make a handsome contribution to the war effort “ Inquiry may be made at the Post Office ”

THE LIMB ON ICE

The principle of refrigeration is no new one in medicine As long ago as 1852 James Arnott[1] was advising the use of a “ benumbing and congealing temperature,” to produce local anæsthesia for surgery and to relieve the pain of trigeminal neuralgia and lumbago , for all of which purposes he seems to have found it uncommonly good For the past ten years F M Allen of New York has been studying the effect of cooling on limbs rendered ischæmic by ligation of vessels, by tourniquets or by vascular accidents Few will quarrel with his conclusion that, when the circulation in a limb is impaired, survival is aided by cold rather than heat , for cold, by reducing the metabolism of the tissues, cuts down the oxygen requirements and thus offsets the diminished blood-supply Moreover, cold arrests the growth of pathogenic organisms and in the ischæmic limb this may make the difference between life and death In animal experiments Allen finds that the survival of limbs cut off from the circulation by a tourniquet is greatly prolonged by cooling, which also lessens the risk of death on sudden release of the tourniquet He suggests that in cases of embolism prompt cooling could extend the period in which embolectomy could be performed well beyond four hours In his latest paper,[2] which is chiefly concerned with diabetic gangrene, he claims that the tourniquet and cooling can produce anæsthesia adequate for a major amputation, and that the method allows the operation to be delayed while the patient's general condition is being improved His aim is not to freeze the limb but to keep it at a temperature round about 5° C , which he achieves by immersing it in ice water, resting it on a solid block of ice, or packing it round with thin flexible bags containing a freezing mixture The tourniquet is applied 5–15 minutes after cooling has been begun, by which time the skin is so much chilled that the application causes scarcely any discomfort Two turns of a rubber tube are used and the tension should be the least that will stop all blood-flow The limb is afterwards buried in ice-bags to a level several inches above the tourniquet Pain and discomfort, it seems, quickly subside in the chilled limb and Allen regards anæsthesia so produced as being fundamentally different from the nerve anæsthesia achieved by anæsthetic drugs Chilling produces what he calls “ anæsthesia of protoplasm ” , the term is vague since anæsthesia merely means absence of feeling, and feeling is the prerogative of the sensorium It is easier to think of refrigeration as inhibiting all protoplasmic activity including that of the nerve-endings Allen considers that it inhibits the shock response as well and that the surgeon thus has the advantage of working in a bloodless shockless field

The time needed to achieve sufficient anæsthesia for operation varies with the depth of the tissue to be cooled , he puts it at 1 hour for an emaciated shin and as much as 5 hours for a thick thigh and states that if it is not possible to cut the sciatic nerve at mid thigh without attracting the notice of the conscious patient and without any change in pulse or blood-pressure there is something wrong in the method of preparation Operation is performed below the tourniquet, which is not removed until the wound is ready for closure Bleeding points are then ligated and anæsthesia persists long enough for suturing to be completed During aftercare the temperature of the limb can be raised by stages to normal level There is no objection, he says, to letting the stump return to normal temperature at once, but by maintaining the chilling several new controls come into play Thus, where poor blood-supply leads to a threat of sloughing in flaps or injured tissues, cooling makes it possible to reduce the oxygen demand to meet the supply Or when the operation, shockless itself, has left damaged tissues which might produce postoperative shock, the danger period can be bridged by cooling In a similar way cooling combined with the application of a tourniquet, he finds, makes it possible to postpone operation in a feeble or toxic patient In such cases chilling is begun on admission and a tourniquet is applied at once and left in position for several days, while the patient is brought to a fit state to withstand *operation* If the tourniquet has been in place for more than a day it must on no account be removed or allowed to slip A few hours before operation another tourniquet is applied an inch or two above the original one, and amputation is performed between the two Allen suggests that the method might have an important application in war wounds, and McElvenny[3] reports a case which seems to support this contention

A man of 50 had had both legs amputated by a train, and when seen an hour afterwards had had tourniquets applied to both thighs and was exsanguinated and profoundly shocked, with a blood-pressure of 30/0 mm Hg He was transfused, the tourniquets were released, bleeding points were picked up, and the stumps were wrapped in gauze soaked in sulphanilamide Eight hours after injury his blood-pressure had risen to 50/10 mm Hg Mud and sand had been ground into the stumps, which were macerated and ragged Within 20 hours of the accident he had developed pneumonia and a foul odour was coming from his wounds His temperature rose to 101° F and his blood-pressure did not improve He was given sulphapyridine and azo sulphamide (Neoprontosil) At this stage the lower limbs were packed in ice to 2 in above the level of tissue injury Pain ceased within an hour, and soon afterwards the foul odour vanished, and the patient who had been delirious became rational He was given three doses of prophylactic *combined sera* and another transfusion He continued to improve and 58 hours after injury his blood-pressure was 110/60 mm Hg with temperature 101° F , bilateral amputation was now carried out under ethylene anæsthesia, and he was transfused on the table The muscles in the amputated limb were found to be in good condition, and the stumps healed with no induration, sloughing of skin or other tissue, or signs of infection The day after operation the patient had his pneumonia crisis, and subsequently made an uneventful recovery

The multiple treatments given make it impossible to assess the part played by cooling in this case, but

Crawford[3] has shown already that the plasma uric acid rises about 0 06 mg for every hour the patient is in labour, and falls to its previous level within 2 or 3 days after delivery In a long labour this factor can lead to a considerable rise of uric acid These three factors are independent of each other and their combined effect is obtained by simple addition The initial level in the eclamptic patient is governed by the severity of the preliminary toxæmia After this there are two curves, one due to the convulsions and the other to the labour These are superimposed on each other the relative position of the two curves depending on whether the eclampsia is ante-, intra- or post-partum Given full clinical details, it is thus possible to calculate the course of the plasma uric acid in an eclamptic patient with reasonable accuracy This work clears away most of the problems about the rise of the uric acid in true eclampsia It leave two points unexplained , the raised level which is usually found in severe hypertensive toxæmias before labour, and the relatively low level in eclamptic patients before the fits begin

FEEDING THE NEWBORN BABY

It is generally agreed that the great fall in infant mortality this century has largely depended on improved feeding methods and Dr Helen Mackay[4] thinks that the neonatal death rate which has remained obstinately high could also be materially lowered by better feeding To this end she has set out her views on the day-to day caloric requirements of newborn babies and suggested a formula whereby their food intake can be regulated From the available figures Mackay puts the caloric value of early human milk and of colostrum at 20 per fluid ounce She also takes this as the caloric value for breast milk after lactation is established and all the artificial feeds she uses are adjusted to give the same figure of 20 calories per fl oz Her next assumption is the customary figure of 50 calories per pound body-weight per day for the average baby's needs, and according to her formula this should be reached in seven days Thus on the first day of life a baby should receive calories equivalent to a seventh of 50 times the body-weight in pounds on the second day two sevenths and so on until the full 50 calorie ration is reached She points out that the formula overestimates the intake of normal breast-fed babies during the first two days of life when breast-secretion is scanty, and rightly emphasises the importance of using these figures simply as guides and not as a rigid system. Turning from the formula to the babies concerned Mackay is able to show that with twenty healthy breast-fed babies the average intake on any one day after the first two days of life is within 3–12% of her schedule, taking those who regained their birth weight by the tenth day A series of 107 consecutive premature babies who had their food intake checked and guided by the formula also made good progress and averaged 1 oz over their birth weight at ten days old For a group of 43 premature babies for whom complete figures are available it was found that their intake for the first ten days of life was within 6% of that allowed by the formula and during the second week of their life intake averaged 53 calories per pound birth weight per day—again within 6% of the formula requirement It seems simple to apply the formula to babies who are completely artificially fed if Mackay's milk mixtures (not explained in detail in her present article) are followed, since they give 20 calories per fl oz The only obvious difficulty is that dividing by seven seldom gives a tidy answer As regards supplementary feeds Mackay points out that purely mathematical considerations do not constitute the whole problem While using the formula as a guide the maternity nurse or supervising medical practitioner must also bear in mind the sucking ability of the baby, the psychological outlook of the mother and the effect on her of a discontented or lethargic baby, the baby's behaviour during feeds the mother's management and the amount of milk remaining in the breast after the baby has finished a feed It is clear, however, that by a formula such as Mackay suggests a check can be kept on the possibility of underfeeding an all too common fault in the early days of breast-feeding and probably the commonest reason for the abandonment of breast-feeding after the mother's discharge from a maternity unit

WASHING WITHOUT SOAP

"Avoid washing" is the usual advice given to a patient with eczema To the patient and his doctor this means avoid soap which irritates sensitive skins, and even normal ones if the exposure is adequate Moreover as Sir Almroth Wright pointed out in a popular lecture many years ago when the epithelium of the skin is thinned by rubbing off or dissolving the superficial layers microbes have a good seed-bed to grow on The abrasive and strongly alkaline soaps used by workers in dyeing chemical manufacturing and other dirty jobs predispose to dermatitis from irritants encountered at work and may produce dermatitis of their own accord Industry and also cosmetic merchants have long realised that there are other cleansing agents besides soaps, for example various sulphonated oils These act by emulsifying the dirt without taking the fat out of the skin , and their pH can be controlled Other detergents are the synthetic wetting agents such as the fatty alcohol sulphates these are good cleansers with a wide variation in pH but they do tend to defat the skin and occasionally act as sensitisers By mixing sulphonated castor oil with 2% of a wetting agent Schwartz[1] has produced a skin cleanser which is safe to use in industry and can even be given to eczematous patients Its disadvantages are its smell and the fact that it does not foam like soap , for these reasons some workmen object to it, especially those not actually suffering from dermatitis This is clearly a field which deserves to be thoroughly explored particularly at present when dermatitis may be a serious trouble among munition workers In the home, however, one feels that it will be a long time before such preparations make much headway against the popular prejudice in favour of ordinary soap and a good lather

HOSPITAL DESIGN

Hospital construction is in a state of transition—it always is of course After a comparatively static period following the Nightingale era, real advances seemed to be occurring during the ten years preceding the present war , but the outbreak of war brought a lull in construction and there is now uncertainty about post-war hospital policy We have in fact arrived at the cross-roads in the principles of hospital building and there is need for intimate discussion between doctors and architects—not to speak of nurses and patients—during the lull so that our ideas may be clarified when the time comes to build again The position was outlined in the history of medicine section of the Royal Society of Medicine on Dec 3 when Mr C E. Elcock, F R I B A opened a discussion on "Hospital building—past present and future The problems fall into two groups questions of policy such as function, size and location , and questions of architectural lay out and detail. As to location Dr R C. Harkness said that L C C experience made it clear that a hospital must be in the area it is to serve if it is to be used to the full Mr Elcock on the other hand felt that space, freedom from noise, fresh air, sunlight and low costs weighted the scales heavily in favour of country sites His main point. in which naturally he had the support of medical officers of health such as Dr J Ferguson of Surrey and Dr W A a particular strain of dog distemper It is hard to see why this should have worked **MARTIN** and **EATON**[4] in California compared the effect of this "complex vaccine" with that of one they made with influenza A virus alone The two seemed equally good, in one institution each reduced the incidence of the disease by more than half in the vaccinated group, while in another institution the results obtained were not impressive with either vaccine The rôle of the distemper virus in the complex vaccine is thus doubtful It must be added that the antibody response produced in man by Horsfall and Lennette's vaccine is of the same order as that caused by the formolised mouse-lung vaccine which has been described from this country[5] The worth of this, for reasons already mentioned, has been neither proved nor disproved It will be obvious, however, that a vaccine can be made more readily and on a larger scale from chick embryos than from mouse-lungs—even, we imagine, in "beleagured island fortresses" such as ours

Annotations

THE GLYPH'S FUNERAL

PERHAPS from indolence, but more probably on account of an obsession inherent in every one of us, familiarity with a subject leads to the increasing use of abbreviations No trade or profession is entirely free from them The Forces are among the worst offenders, but even the Cloth is not blameless, as a glance at Cruden will testify Again no sooner have we learnt to write legibly than we slip imperceptibly into the reprehensible habit of trailing our words into nothingness The pathogenesis of the decay in calligraphy is still in dispute, but it is significant that when the subject is discussed in public the plight of the physicians rarely goes unnoticed Our hieroglyphics have become a standing joke in the music-halls while pharmaceutical students submit with good grace to a course of instruction on the reading of "illegible" prescriptions Even within our own ranks we can hardly deny that the combination of dog Latin, freakish handwriting and bizarre symbols has brought us to a pretty pass This cult of medical obscurantism almost certainly originated in a desire to create an atmosphere of erudition otherwise difficult to achieve, and at the same time to bamboozle patients who are intelligent enough to show an interest in the names of drugs which they have been instructed to swallow That the practice of illegible prescribing is a vicious one and fraught with potential danger to the patient has been recognised in Scandinavian countries where offenders are liable to imprisonment without the option of a fine "Depend upon it, sir," said Dr Johnson, "when a man knows he is to be hanged in a fortnight, it concentrates the mind wonderfully" It may be that nothing short of a smart penalty will remedy the present state of affairs, but there are one or two reforms which could be effected without delay In the first place, prescriptions should be written in English With rare exceptions the Latin which is now used would bring a blush to the cheek of a fourth-form boy And the banishment of our grotesque symbols ℈, ʒ and ℥ is long overdue, however fond we may be of them When these curious markings have degenerated into mere zig-zags—a process which seems inevitable when a doctor takes a pencil in his hand—the drachm sign may be mistaken for the ounce and an eightfold dose given in error Thus a patient who should have had six drachms of paraldehyde was actually given six fluid ounces by a nurse, and a man s life was t away[1] The B P and now the N W F recommend quantities of solids should be expressed in grains (gr) ounces (oz) Here the ounce is avoirdupois and is to 437 5 grains Volumes of fluids should be stated in minims (min) and fluid ounces (fl oz) It may be objected that "min" might be confused with minutes (5 min castor oil every 20 min), but the context should obviate this difficulty The National War Formulary recommends a capital G as the symbol for gramme. This will differentiate even more clearly between grain (gr) and gramme (g), and will eliminate the uncertainty which arises from unconventional abbreviations such as grn and grm To make doubly certain it might be well to retain the traditional practice of writing min (for minim) and gr (for grain) before the numeral and min (for minute) and g or G (for gramme) after it Roman figures too have long been a curse to the dispenser, they are an anachronism which should no longer be tolerated Mistakes are far less likely to happen when Arabic numerals are employed A recognised code of abbreviations is highly desirable, and the B P and N W F have shown how easily it might be acquired by every practising doctor Only custom and apathy stand in the way Now that the season is at hand for turning over new leaves, we might resolve to lighten the dispenser's task by prescribing accurately, legibly and simply

PLASMA URIC ACID IN ECLAMPSIA

IT has long been known that the plasma uric acid is raised in eclampsia, sometimes to 15 mg per 100 c cm or even higher The reason for this rise has hitherto not been clear, but there has been a general opinion that it is part of the metabolic disturbance due to the "toxæmia" M D Crawford[2] has now made a careful study of the subject, following individual patients through the stages before the onset of eclampsia and then through the convulsive phase and for some days after Analysis of the findings reveals three basic factors *The factor* which comes first in time is the severity of the preceding hypertensive toxæmia This requires a preliminary consideration of the findings in patients who are not destined to have any convulsions During the last few days of pregnancy the mean plasma uric acid in normal women is 3 9 mg, in women with mild toxæmia it is 4 4 mg, and in women with severe toxæmia it is 6 4 mg per 100 c cm It might reasonably be expected that a patient who is on the verge of developing eclamptic convulsions would have an even higher uric acid, but this is not so If she has few or no symptoms before the onset of fits her uric acid is normal, if she has severe previous symptoms her uric acid is moderately raised but is usually below 6 mg From the present figures it appears probable that a severely toxæmic patient is not in danger of eclampsia if her uric acid is in the range of 6 5–9 7 mg The second factor is the effect of the convulsions themselves If the patient has a single fit, her uric acid rises about 1 mg in the next hour and then more slowly for the next few hours The greater the number of fits the greater the rise, so that a patient who has a dozen fits has a uric acid about 6 mg above the initial level within 6 hours after the onset of the fits The high level is maintained for 6–24 hours and the uric acid then falls at about 0 5 to 1 mg per day, the rate of fall depending on the type of eclampsia and the degree of oliguria The same type of rise was found by Crawford to follow convulsions produced artificially in non pregnant patients for the treatment of various psychoses, and also similar convulsions produced experimentally in rabbits The second factor thus appears to be the muscular effort of the convulsions *It* accounts for most of the elevation of uric acid found in patients brought into hospital after the eclampsia has begun The third factor is the duration of labour

Special Articles

THE ADULT SCARLET-FEVER CONTACT

W L SCOTT M C, M D GLASG
SECOND MEDICAL OFFICER TO THE POST OFFICE

In a previous article dealing with the whole question of infectious-disease contacts (*Lancet*, 1937, 2, 397) Post Office procedure was explained, and it was shown that, from 1898 until 1937, there had been no recorded case of an employee contracting any of the Post Office scheduled infectious diseases from a contact who had been allowed to remain at work The department is the largest single employer of labour in this country and in 1936 the staff amounted to approximately 260,000

The rules require a contact of smallpox, plague, typhus or cholera to remain at home until all the necessary disinfection of the premises has been carried out and the Chief Medical Officer is satisfied, after medical examination of the contact, that resumption of duty may take place with safety, if necessary under medical supervision A contact of diphtheria is not allowed to resume duty without a medical certificate of good health He reports for duty in the ordinary way, but before being allowed to begin work he is sent to the medical officer for examination If a throat-swab is considered necessary, absence is allowed pending the result Enforced absence is not required for contacts of such diseases as measles, german measles, chicken-pox, mumps, erysipelas, whooping-cough, encephalitis lethargica, enteric fever and epidemic cerebrospinal fever, unless the medical officer of health, for some local reason advises quarantine Each contact, however, is warned that he or she must not nurse or otherwise attend upon the invalid, but, if it is essential that any of these functions should be performed by the contact, leave is allowed without pay Boys and girls are usually kept under the special observation of their supervising officers during the incubation period and the medical officer is consulted if they show any signs of ill health during the quarantine periods

Up to 1937 scarlet-fever contacts were required to remain at home until the patient had been removed to hospital and disinfection carried out or had been satisfactorily isolated at home, or the contact had removed to other lodgings For some forty years Post Office procedure as regards scarlet-fever contacts was thus in advance of its time, the full quarantine period having been reduced without ill effects to other members of the staff During 10 years' observation (1927–36), the number of contacts of scarlet fever in the Postal Service amounted to 17,844 and of these only 1 in 251 (0 39%) developed the disease within a month of the termination of the illness of the invalid Enforced absence from work—even with this considerably reduced quarantine period—had cost the department the equivalent of 52 working years during these 10 years, the average loss in time being 1 04 days per contact By ordinary standards this loss was small compared to what would have been incurred had the normal quarantine period, still required by many other employers, departments, and services been insisted on

In 1937, with the approval of the Ministry of Health, this procedure for scarlet-fever contacts was finally discontinued, and the contact is now required to report for duty in the ordinary way but, before being allowed to begin work, he or she is sent to the medical officer for a report on his or her health This brought the treatment of contacts of scarlet fever under exactly the same procedure as had already been in force for diphtheria contacts, and the alteration in the rules was considered to be fully justified since, for all practical purposes, the staff consisted of non-susceptible adults A small proportion of Post Office employees are recruited between the ages of 14 and 16, but the majority are between 16 and 60 years of age Scarlet fever is a disease which mainly affects people between the ages of 9 and 15

In view of the small numbers of contacts who subsequently developed the disease and the fact that no spread of infection had followed this long-established policy it was concluded that the risk in abolishing quarantine would be negligible During the three years 1938–41 [illegible] er the abolition of quarantine—of the 2181 reported instances of contact with scarlet fever only 1 in 131 (0 22%) subsequently fell ill of the disease within a month of the termination of the invalid's illness, and again no infection of other employees was traced to any of the contacts

Research workers, notably Allison,[1] have within recent years demonstrated that the causative streptococcus can be isolated in a living state from dust bedding, belongings and clothing, and it would be idle to deny that such organisms could be carried by any contact This discovery has perhaps lent a certain amount of support to the older policy of segregating contacts But in Post Office experience a healthy contact does not in fact convey infection in ordinary circumstances

Naturally, local opposition to Post Office practice has occasionally been encountered from those whose views on the necessity for the full period of quarantine have undergone no change during the last half century , and inquiry has shown that in various industrial concerns, public services and departments exclusion from work of contacts of scarlet fever—often for the whole incubation period—is still the rule, but without, it should be noted, any control over what the contact may do, or with whom he may mix, while on enforced absence from his normal work Most of such concerns are in the same position as the Post Office, that is to say, they employ or control a non-susceptible adult population , and the loss of working hours as a result of this insistence on a routine quarantine period for all contacts of scarlet fever—and often, of course, with all the other common zymotic fevers—must in total be enormous This loss is, in the light of Post Office experience, wholly unnecessary

CONCLUSIONS

Post Office policy has clearly demonstrated that, provided the contact is in good health, remains under medical observation if considered necessary, and is not nursing or attending the invalid, he or she may safely go about his or her business without danger to others and without interruption This is the basis of all infectious-disease procedure approved by the Ministry of Health, and it seems desirable especially now when man-power is so important, that the bogy of the adult scarlet-fever contact should finally be laid

I am indebted to all those who have assisted in the preparation of these figures, and particularly to Miss D A Neale of the Medical Branch

LIGHT ON CORTICAL FUNCTION

THAT a man may lose a considerable amount of brain tissue without gross deterioration of intelligence is an old observation Even removal of an entire hemisphere on account of neoplasm need not lead to incapacitating mental changes Four cases of the kind have been reported by Karnosh and Gardner[2] this year, two of the patients being women and two men , one woman died 29 days after the operation from meningitis, one died of a fall 18 months later, and the two men are surviving The right hemisphere was removed in each case, and speech was affected in none, although one of the patients was left-handed The more outstanding physical results of the operation were left hemiplegia and left hemianopsia, but other more trifling residues—such as defective sense of smell—were easily detected The mental changes were more elusive , the patients on recovery were alert and more vivacious than before quick in facetious repartee, but all showed wide mood swings and found it difficult to concentrate and to carry out deliberate and protracted mental processes The woman who died of a fall was regarded by her family as almost normal, yet they spared her all responsibility and she was not called upon to initiate any new programmes for herself or others One of the surviving men was a restaurant keeper who after the operation lost his keen interest in his business, disposed of serious matters with a shrug and was not greatly concerned by the financial affairs of his family , yet he seemed much as usual otherwise, except for an increase in his natural high spirits The other man was definitely changed for the worse , he became coarse in his conversation and untidy in his dress, made no attempt to return to his

Bullough of Essex was that the building for the sick must in future be a part of a local centre for preventive as well as curative medicine Such a scheme, in which the hospital itself would be merely a necessary detail of the whole, had been worked out at Grantham but postponed owing to the war A new idea was embodied in the Harvard Hospital (somewhere in Wessex) which was a base for a field unit with its laboratories, combined with a hospital for infectious diseases Mr Elcock favoured the policy of using hospitals for education in healthful living the building was as important as what happened inside it As regards size it seems clear that the day of small scattered special hospitals is over For historical reasons, as Dr Harkness pointed out, the isolation hospital, sanatorium, maternity hospital and so on had risen independently, there was no reason why they should not now be grouped and the isolation of their medical and nursing staffs ended This would accentuate the importance of circulation, as many as 20 traffics might have to be considered in a modern general hospital Mr Elcock claimed that his continuous veranda type of ward, with beds parallel to walls, ensured a far larger amount of sunlight per patient, this had been shown experimentally at the Building Research Station and in practice at the Hertford County Hospital On one point both architects and doctors were agreed—the need for specialisation in hospital construction by both professions The day of the benevolent amateur is over The local architect's plans, adapted by clinicians with the matron called in as an afterthought, produce a building which is often more cottage than hospital The Emergency Hospital Service has revealed the need for specialist hospital officers The effective coroner is a blend of lawyer and doctor, should not the central authority, at least have on its staff a doctor who is qualified in architecture ?

RISKS OF PARACHUTE-JUMPING

NEW methods of warfare tend to produce new types of injury as missiles and machines change, and to some extent treatment changes accordingly, although basic surgical principles remain unaltered The pathology of parachute jumping is the latest offspring of aviation medicine, itself so recently a lusty infant, and in what must be one of the first reviews of these injuries in English, Tobin Cohen and Vandover[1] have surveyed the accidents occurring during the first year of parachute training in the United States They note that the four phases of a jump are each associated with a special group of injuries The first arise at the time of leaving the plane and are due to entangling of equipment or failure of the parachute to open, and these are usually fatal, although in one case where the jumper got hooked to the tail of the plane he escaped with a dislocated hip In the second phase, when the parachute opens the shock may produce serious abdominal or thoracic injuries, a danger that may be lessened by distributing the shock over as wide an area of the body as possible During the third stage of actual descent, diverse lesions may occur, and in this connexion Boothby, Benson and Lovelace[2] have pointed out the risk of fatal anoxia when the pilot has bailed out from over 30,000 ft during his descent to sufficiently oxygenated air at 18,000–20,000 ft The injuries on impact compose the fourth and by far the largest group, consisting mainly of more or less complicated injuries to the lower extremities, and fortunately these can be minimised by intensive ground-training in alighting before actual jumping is begun In all 2 4% of the jumps made were associated with some injury but only a quarter required hospitalisation, 80% of these major injuries were fractures, none of them compound, half of which were malleolar, though fractures of every bone of the lower limb were recorded Rather unexpectedly the os calcis was fractured only once Falls on the outstretched hand resulted in an occasional fracture of the clavicle, humerus, or radial head The frequency of malleolar fractures must be ascribed to uneven landing associated with cross currents, unskilled guidance of the parachute, and irregular terrain, these factors combining to produce a violent temporary shearing force across the ankle joint The incidence of these injuries, which are of the type that tend to unfit a man for further jumping, is small, and Tobin and his colleagues attribute this to careful preliminary training in the art of jumping This paper leads to the reflection that parachute troops are one of the few groups of fighting men separated from their medical services during active warfare, but perhaps this problem, too, will be solved in time

DRIED AND CONDENSED MILKS

THE deficit of liquid milk for the main body of the public owing to its welcome increased intake by children and pregnant and nursing mothers, and the large import of dried and condensed milks from the U S A and Canada naturally raise the question of the relative nutritive values of these commodities How far does condensation and drying lower the food values of milk? People who have heard that cooking destroys vitamin C rush to the conclusion that heat treatment of milk destroys *all* its nutritive value They may take comfort from an article by S K Kon[1] of the National Institute for Research in Dairying in which he gives a comprehensive table of the constituents of various forms of milk and the loss of them, if any, in manufacture The loss is remarkably small, except in vitamins B_1 and C, and since milk is of small value in supplying these vitamins it matters hardly at all from a dietetic point of view whether milk is taken pasteurised, sterilised, condensed or dried Milk is valuable mainly for its first class protein, its calcium and its vitamin A It makes a substantial contribution of riboflavin but its values for vitamins C and D are low Fortunately vitamin A and riboflavin are not reduced at all even by drying, nor is the calcium rendered less available There is possibly some small reduction of the biological value of the proteins, but it is negligible Even the drastic treatment of milk in spray drying destroys only 10% of its B_1 and 20% of its C Dried and condensed milks are therefore not to be despised by anyone, and there are hygienists who look forward to the day when milk will be purchasable only at the grocers

A SUPER DUST MAN

John Switzer Owens whose death is announced qualified at Trinity College, Dublin, in 1892 and took his M D four years later He played truant from the Medical Directory to reappear in 1912 with high engineering qualifications as hon secretary of the Committee for the Investigation of Atmospheric Pollution under the chairmanship of Sir Napier Shaw, director of the Meteorological Office Of this committee our Mr Vasey was also a member, much of the work was done in THE LANCET laboratories, and the reports appeared as supplements in our columns Owens had the bonhomie and the drive to make any collective investigation a success, he had a vision of what England might be without smoke, and his agile mind was constantly devising new and better methods for trapping and measuring the particles of dust in the air He was also the instigator of the Coal Smoke Abatement Society and wherever linen can now be hung out to dry without getting grimy, or the reader in a city garden can turn over the page of his novel without first blowing the smuts off it, the name of Owens should be held in honoured memory

GENERAL MEDICAL COUNCIL

(Continued from p 709)

Alleged Falsification of Temperature Charts

The case of *William Blackwood* registered as of Tregenna, Camborne M B Edin (1902) who had been summoned on the following charge —

That being a registered medical practitioner and a medical officer of a maternity ward provided under a scheme of the Cornwall county council at the Camborne Redruth Miners and General Hospital Redruth, (1) You in or about the month of September 1939 wrongfully agreed with Harry Lee Shimmin another registered medical practitioner, to commit a breach of the rules made by the county medical officer of health for Cornwall for the management of the said maternity ward and then in force in respect of such ward (2) You falsified or caused to be falsified the records of the temperatures of patients in the ward for whom you were responsible, and in particular you falsified or caused to be falsified the records of the temperature of the following patients namely, (a) Mrs Edna Carr of The Croft, Porth Newquay on certain dates between May 7 and 25, 1941 (b) Mrs Ethel Alice White of 4 Maer Down Bude, on certain dates between April 7 and 27 1941 and (3) In the cases of Mrs. Edna Carr and Mrs Ethel Alice White you failed to notify the County Medical Officer of Health as required by the said rules

Respondent was represented by Mr A A Pereira instructed by Messrs Le Brasseur and Oakley solicitors on behalf of the London and Counties Medical Protection Society Mr G Howard instructed by Messrs Waterhouse and Co for the General Medical Council applied that the cases of Drs Shimmin and Blackwood should be heard together Mr Pereira objected that the charges had not been adequately particularised in the matter of the temperature charts He did not in fact, know what document his client was alleged to have falsified, and joint hearing might prejudice his case The Legal Assessor advised the council that the two cases should be heard together, and the members so voted by a show of hands

The similar charge against *Harry Lee Shimmin* registered as of Belmont Redruth M R C S (1926), read in similar terms (*mutatis mutandis*) as regards preamble and clause I and continued —

(2) You falsified or caused to be falsified the records of the temperatures of patients in the ward for whom you were responsible (3) In the case of Mrs. Cornish who was a patient in the said ward on May 26th 1941 and subsequent days (a) You failed to notify the medical officer of health for the district as required by the Puerperal Pyrexia Regulations, 1939 (b) you failed to notify the county medical officer of health as required by the said rules (4) You failed to notify the Medical Officer of Health for the district as required by the Puerperal Pyrexia Regulations 1939, in the case of (a) Mrs Violet Ward who was a patient in the said ward between Sep 7 and Oct 15 1940, and (b) in the case of Mrs Phyllis Waters, who was a patient in the said ward between Jan 23 and March 10, 1941

Mr Howard cited the relevant regulations and the rules drawn up by the county medical officer of health, and said the respondents had within the relevant period expressed their entire agreement with those rules Letters between county M O H and respondents showed that their attention had been called to the rules and that they concurred with them in September, 1939 He put in the temperature charts and pointed out that Mrs Carr's and Mrs White's charts showed no temperature notifiable under the rules or regulations but Mrs. Cornish's, Mrs Ward's and Mrs Waters's clearly showed circumstances requiring notification It was claimed that the first two charts had been falsified

COUNTY M.O H. S EVIDENCE

Dr R N Curnow testified that soon after his appointment in March 1939 he had drawn up rules governing the Redruth Maternity Hospital and had later consulted Dr Blackwood and also the other medical staff; the rules had been gone through with both respondents who had accepted them without criticism or objection In the ward it was the custom for the nurse to take temperatures and enter them in a book The sister subsequently charted them, and the doctors saw them on their rounds He produced the original charts and confirmed what Mr Howard had said about the records then shown He had received no notification in respect of any of them Dr C H Rivers the district medical officer, would have received the certificates and forwarded copies to him In June, 1941 he had received information from the matron and had held an inquiry concerning Mrs Cornish who had died Respondents had been present, Sisters Davies and Love had made statements in their presence Sister Davies said she had for some time been falsifying charts with the knowledge of the doctors Dr Blackwood had pressed her to say that this had only been done with temperatures under 100° F she had replied that she could not be sure

Cross-examined, Dr Curnow said that on his visit to the hospital he had not noticed the absence of a copy of the rules, and agreed that in his letter to Dr Blackwood he had used the word "routine," not "rules" The rules had been sent to Dr Blackwood, who had telephoned that he accepted them and would hang them in the ward He could not accept the suggestion that Dr Blackwood had refused to exhibit them He had never seen the ward routine carried out until the inquiry he had not known of the existence of a temperature book in this particular ward, though he knew of it as a very general custom He had never examined the book Mrs Cornish had died on Whit-Sunday and his assistant had at once gone down to conduct an inquiry He did not remember a telephone conversation with Dr Blackwood when the latter had expressed astonishment at Sister Love's statement that temperatures were customarily falsified It was correct that when respondents had arrived at the subsequent inquiry on the Thursday, June 5, conducted by him they had not known that any accusations were to be made against them Sister Davies had then said that she had been initiated into the custom of false entry by her predecessor and that it was a common custom She had said it was no use checking the charts by the temperature book because that also had been falsified, she had, in fact brought the book but he had never checked the charts by the book and there was nothing else to check them by He had complained at the inquiry that the blood-pressure readings were not recorded on the chart, Dr Shimmin had at once said that he had taken the readings and called them out to the sister who had forgotten to enter them Sister Love had made and signed a statement that charts had been falsified he had asked her what the falsification was, and she had said that the first rise of temperature was recorded, but a second was not entered until discussion with the doctors had determined whether or not the case should be notified He had asked for particulars, but she had been unable to give any She had not said that the doctors had ever instructed her in any specific case but she had said that the doctors knew all about the system She had said that she had repeatedly drawn Dr Shimmin's attention to Mrs Cornish's high temperature and asked him to notify and he had taken no notice—but she had added that he was taking every care of the patient The work of three doctors was at this time being done by two, all doctors in the area were very heavily overworked at this time He had made an offer after the inquiry, to appoint a county obstetrician under whom respondents would perhaps work if the committee agreed He had informed the committee that respondents had offered their resignations in writing He had accused them at the end of the inquiry of trickery, but his letter to Dr Blackwood dated June 25, 1941 announcing the committee's agreement to the appointment of an obstetrician, and Dr Blackwood's reply contained no suggestion of a charge of serious misconduct He agreed that it would be to the advantage of the doctors to remove difficult cases to the puerperal-fever home He did not agree that the regulations were unpopular, though they certainly involved extra work and inconvenience There had been no case of puerperal fever in the ward during the period of Dr Shimmin's attendance

In reply to the President, he said he had drawn up the rules because the state of affairs was unsatisfactory, he had drawn up similar ones in Derby and had submitted those (but not the Cornish ones) to an official of the Ministry of Health. The maternity ward was governed by a voluntary body but administered jointly by them and the county council He had no statutory powers to enforce his rules No action in a civil court for infringement of the Puerperal Pyrexia Regulations had been discussed The clinic to which the patients were to be removed was 10 miles from Redruth there was one isolation bedroom in connexion with the ward The appointments of staff were recommended by the hospital committee subject to the approval of the county council Dr Blackwood had been appointed a representative of the county medical officer in administrative charge of previous occupation of book-keeping and though full of grandiose schemes failed in several small projects financed by his parents because after a burst of enthusiasm at the outset, he lost interest in a few weeks and failed to carry on.

These findings seem to fall into line with observations now being made on patients treated for chronic mental disease by prefrontal leucotomy. This, though much less destructive, of course, than removal of an entire hemisphere, is a bilateral operation and there can be no question of one hemisphere taking over immediately functions lost by the other. An account of eight cases of this operation (which consists in division of the subcortical fibres of both frontal lobes) was reported recently in our columns[3] by Hutton, Fleming and Fox. At a meeting of the Royal Medico-Psychological Association on Nov. 26, Dr. Lilian Hutton described the personality changes in several of the 15 patients so far treated by prefrontal leucotomy in connexion with the Burden Neurological Institute. When they recover from the operation these patients may show no intellectual defect as judged by ordinary tests; they may still give an intelligence quotient of 100 or more. But specially devised tests seem to show that they have lost the power of initiating stimuli within themselves, though they respond as readily as ever to external stimuli. She described the case of a man with obsessional ideas of unworthiness; Dr. R. S. Hodge who had been first consulted by this patient told how at the interview the man had refused a confortable chair, had fetched himself a hard one and, sitting on the edge of it and wringing his hands, had talked of his unkindness and wickedness. On leaving, he had returned to the waiting-room and swept up the cigarette ash he had dropped on the carpet. Months later, after the operation, he had come again, cheerful and active and in full control of his affairs. The patient talked enthusiastically of his recovery; but on his way out caught sight of the waiting-room door and darted in. After a moment he came out grinning; he said "I still do that kind of thing, but"—tapping his chest—"it no longer hurts me here." The sight of the waiting-room door, Dr. Hutton thought, was the stimulus setting in train the old obsessional act; but she believes that, lacking their former emotional accompaniment, such acts will gradually fade out, especially since they are no longer initiated spontaneously but require an external stimulus to provoke them. Dr. Hutton described how this man had responded to a series of well-known phrases both before and after treatment. Before his operation the words "Send us victorious" had caused him to finish the verse and then go on immediately "I'm possessed by myself." Similar phrases produced a momentary response followed by an immediate return to the obsessions and images which were engrossing his attention. After the operation, when the initial symptoms had subsided, the phrase recalled to him a visit of the King to France during the last war. When the stimulus was provided, then, he could respond with the appropriate memories and recount them amusingly; thus his relatives saw little change in his personality except for the better. Nevertheless he had lost some capacity for abstract thinking, as was clear when he was asked to say what he meant by a dog. His first reply was "A dog is a dog. What more can I say"? But after a little help and encouragement he said "Well a dog has four legs. It might be black or brown. It might be a hunting dog or a house dog." Thus he described a series of dogs in concrete terms but made no attempt to give an abstract conception of a dog. This suggested to Colonel P. K. McCowan that the condition produced was a mild dementia, and to Prof. J. H. Macdonald that the effect of the operation was merely to make the patient more amenable and tractable, but to rob him of the power of discrimination and selection from past experience which distinguishes man from the ape. Dr. Hutton felt that it was impossible to describe as dementia a state in which the subject could achieve his normal I.Q.

In speaking of the mechanism of the change she trod among quicksands and was justly tentative. She suggested that we can only bring an object into the perceptual field of the appropriate sense or senses by making the necessary movements of adjustment—we turn the eye to an object and focus it, for example; and as we do this we attend to the object. We are able to maintain or recall images, she thinks, by reproducing or recalling the movements necessary for the original perception of such images, and in this way we are increasingly able to recall the past and anticipate the future. In the chronic types of mental disorder treated by prefrontal leucotomy—melancholia, anxiety states, obsessional and compulsive neuroses and schizophrenia—the patient's attention is devoted almost exclusively to maintaining the ideas and images out of which he creates his illusory world; he does not attend fully to the real world. If the maintenance of his ideas and images depends on recall of the muscular adjustments which were necessary at their original inception, division of pathways concerned with organised movement in the prefrontal lobe has a rational basis. With those pathways divided the patient is at liberty to respond to ideas and images prompted directly by the environment—to attend to reality—and his behaviour will therefore be more appropriate. Dr. F. L. Golla suggested that a late study of these cases may show that the disability due to loss of spontaneity and initiative becomes modified. The central nervous system is labile, and if some tracts are cut others tend to take over their functions; the neurons are not reconstituted, but the patient learns new ways of performing old tasks.

REVISED B.P.C. FORMULÆ

A SUPPLEMENT to the B.P.C. 1934 brings the formulæ in part 3 into line with the four addenda to the B.P. 1932 and with the recommendations of the Therapeutic Requirements Committee and the N.W.F. Most of the changes made aim at economy in flavouring agents, glycerin, sugar, alcohol (tinctures), olive oil, lard, liquid paraffin, and so on, but many new formulæ have been added to bring in drugs and preparations which have become fashionable since 1934. The emulsions have been drastically overhauled. Emulsio olei morrhuæ and emulsio olei morrhuæ et creosoti are *not seriously* changed, but in the emulsions of cod-liver oil with glycerophosphates and hypophosphites the cod-liver oil is replaced by vitaminised oil and we must write emuls. ol. vitamin. c̄ glycerophosph. or c̄ hypophosph. The emulsio paraffini liquidi of the N.W.F. containing 25% liquid paraffin may be dispensed when emuls. paraff. liq. c̄ agar is prescribed. The paraffin content of all the compound emulsions has now been fixed at 25% and agar has disappeared throughout. Potable water is sanctioned in place of distilled except in injections, and for these processes of sterilisation similar to those given in the fourth addendum to the B.P. 1932 have been adopted. There is a new injectio quininæ dihydrochloridi containing gr. 52½ in 4 fl. oz. of normal saline (dose 2½–5 fl. drachms intravenously). Linimentum album can no longer be called "egg liniment," for its egg has gone. The new linimentum methylis salicylatis (N.W.F.) has lost its menthol, eucalyptus and camphor and consists simply of methyl salicylate in rape, arachis or cottonseed oil. There are several new liquors, including opii camphoratus concentratus, and Ringer lactatis as well as those in the N.W.F., and a new lotio benzylis benzoatis. Mistura alba now contains gr. 90 of sodium sulphate to the fl. oz. in place of its gr. 120 of magnesium sulphate. Mistura ammonii acetatis composita has sodium in place of potassium citrate, and dispensers are authorised to substitute sodium for potassium salts elsewhere whenever suitable. The bismuth mixtures remain, but an alternative is provided in mistura magnesii trisilicatis composita. Zipp (zinc oxide, iodoform and liquid paraffin) is now included as well as bipp, and so are the pigmentum iodi and the pigmentum violæ crystallinæ compositum (pig. triplex) of the N.W.F.

THE fact that goods made of raw materials in short supply owing to war conditions are advertised in this paper should not be taken as an indication that they are necessarily available for export.

THE Minister of Labour proposes to apply sec. 66 of the Factories Act, 1937, to toxic anæmia. Draft regulations may be had from H.M. Stat. Office.

MESSRS. JOHNSON & SONS (Hendon) ask us to say that supplies of Estersil are again available.

---

[3] Hutton, E. L., Fleming, G. W. T. H., Fox, F. E. *Lancet* 1941, 2, 3.

to Truro and had asked Dr Shimmin about it several nes, he had replied that she was not suffering from erperal sepsis, her wound was perfectly alright, her chia were normal and therefore there was no need for r to go to Truro

Cross-examined she said Mrs Cornish was in a room y herself, but not in special isolation She had had esarean section, was a thyroid case, and developed neumonia Her mental condition had not been normal he herself had made a wrong entry in the case of Mrs arr, and possibly also in the case of Mrs White

* * *

Mr Pereira submitted that he had no case to answer r Howard replied, and after deliberation in camera the resident announced that the *facts alleged* against Dr lackwood *had not been found proved* to the council's atisfaction and the case against this respondent was herefore ended The same applied to charges 1 and 2 gainst Dr Shimmin but the council would like to hear he defence to charges 3 and 4 -the cases of Mrs Cornish, rs Ward and Mrs Waters

RESPONDENT'S EVIDENCE

Dr Shimmin testified that Mrs Cornish came in with bstructed labour and thyrotoxicosis and was very ill nd exhausted on admission, with a raised temperature 100 4° F) She had an enlarged thyroid, with pulsating eins in the neck, and was ashen and clammy Her eart was dilated She had had two previous forceps eliveries After a period of expectant treatment, he nd Dr Blackwood had performed cæsarean section Next morning she seemed fairly well, but the next day here was failure of compensation and mental disorder The following day (the third day) crepitations appeared t the bases of both lungs On the fourth day she vas a trifle better On the fifth day there were signs f consolidation in the right base and her heart was ilated He had seen her three times that day, nd at 3 o'clock the following morning she had collapsed nd died The doctors made no case-notes in the ospital, the notes on the chart were made by the ursing staff He had no private case-record There had never been any indication of puerperal septicæmia Sister Love had seemed to him more worried about the patient's temperature than about her condition She ad not asked him to notify it He thought now that he case should have been notified but at the time he had not regarded it as puerperal septicæmia He knew also now that the cases of Ward and Waters should have been notified He had never at any time notified the county M O H on paper his custom was to telephone He had failed to telephone about these cases because he forgot, it was an oversight He had not notified the district medical officer of Mrs Ward because the patient had pyelitis and not septicæmia Mrs Waters was a ase of Bartholin's cyst obstructing a vagina full of aricose veins, and adherent placenta with severe æmorrhage He had been with her from 1 A M to A M He had telephoned Dr Curnow who had advised ruro, and respondent had said she would die in the mbulance He had thought that his telephone notification to Dr Curnow would cover the statutory requirement, he now knew that it did not

Cross examined, he said he had never seen a copy of Dr Curnow's rules, but had agreed to follow them He was aware that the rules and the regulations referred to puerperal pyrexia, not to puerperal septicæmia Mrs Cornish had been given M & B 693 for the pneumonia Mrs Waters had had Prontosil because of the amount of instrumental and manual interference required in her case Mrs Ward had had prontosil because it was a ward routine to give it with a rise of temperature He admitted that his attention had been drawn to the definition of puerperal pyrexia in 1939 He thought he had done his whole duty by elephoning Dr Curnow and acting on his advice In eply to members of the council, he said he still did not hink Mrs Cornish's temperature had anything to do ith a puerperal condition He had a fair experience f puerperal septicæmia.

* * *

Mr Pereira put in two statutory declarations as o character, from Dr Rivers, district M O H, and Dr T M Reed He addressed the council, which deliberated in camera after which the President announced that *charges 3 and 4 had been proved* to the satisfaction of the council which took a grave view of these derelictions of duty and trusted that the proceedings would cause respondent to be more scrupulous in future He had not directed the registrar to erase his name

Parliament

ON THE FLOOR OF THE HOUSE

MEDICUS M P

THE National Service (No 2) Bill was introduced last week by a three-day discussion of a motion moved by the Prime Minister

"That in the opinion of this House, for the purpose of securing the maximum national effort in the conduct of the war and in production, the obligation of National Service should be extended to include the resources of woman power and man power still available, and that the necessary legislation should be brought in forthwith"

The procedure is unusual The usual way in which bills are presented is to have a purely formal "first reading" which is just a reading out of the title of the bill without discussion, followed by a "second reading" on which a general discussion takes place After this comes the "committee" stage, in which detail amendments are made and eventually a "third reading" which again allows opportunity for a general discussion and sometimes amendment This three-day debate of the motion was, as the Speaker said in the course of discussions on the form of a proposed amendment, a reversion to an old practice "in the form of a motion" which was a de facto first reading To the original motion by the Prime Minister an amendment was moved by Mr George Daggar, and seconded by Mr William Dobbie, and eventually supported in the lobby by 40 votes of which 33 were Labour, three Liberal, one Independent, and three I L P To these must be added the two Labour "tellers" Mr Dobbie and Captain John Dugdale, now an education officer with a division and formerly private secretary to Mr Clement Attlee, Lord Privy Seal

The amendment proposed that

"this House, while assenting to the extension of the principle of compulsion to the man power and woman power still available, is of opinion that, in order to secure the full utilisation of national resources in the war effort, it is essential that industries vital to the successful prosecution of the war, and especially transport, coal mining and the manufacture of munitions, should be brought under public ownership and control, and that the necessary legislation should be brought in as soon as possible"

The debate was of a high order but represented a clear-cut cleavage of opinion between those who believe the man-power and woman-power situation can be effectively dealt with without a drastic extension of national control of munitions production, transport, coal and power and those who do not The vote of 40 for the amendment is not a large proportion of the House, but in view of the strong appeals for "unity" made by Mr Attlee to the Labour Party members meeting and the strong pressure put on M P s to refuse to support the amendment the registering of so many as 40 votes in the lobby in its support indicates a considerable divergence of opinion

* * *

The debate was not conducted on party lines Those proposing national ownership and control of certain services did so from the standpoint of war efficiency Those supporting the amendment were hoping that Mr Ernest Bevin, who wound up for the Government on the third day, would indicate that property considerations were to be treated as ruthlessly as personal considerations in the carrying out of the new and vast national mobilisation, but they were not satisfied Mr Bevin said, in answer to arguments for the amendment, that if it "is seriously advanced that there should be further requisitioning of either property, services or industry the Government will examine any specific claim, and will deal with it on its merits" This statement was felt to be so tepid as to be unacceptable Mr E Shinwell who had wound up for the Labour Party, quoted a declaration of the Bournemouth Labour Conference of 1940 which authorised that ward He had looked through the temperature books but had found no evidence of alteration, they were written in pencil Mrs Cornish's death after cæsarean section had been certified to him as due to toxic thyroid and lobar pneumonia, there had been no autopsy

* * *

Mr Pereira said that the death-certificate gave "acute dilatation of the heart, thyrotoxicosis, pneumonia, cæsarean section"

Mr Howard put in two statutory declarations from Dr Rivers, district medical officer for Camborne and Redruth, stating that he had never received notifications under the Puerperal Pyrexia Regulations in respect of Mrs Cornish, Mrs Ward and Mrs Waters

NURSES' EVIDENCE

Miss M Commerford declared that she was a state-registered nurse and certified midwife and had been employed at the Redruth Hospital from February, 1939, to March, 1940, becoming sister in charge of the maternity ward in September, 1939 She had had no conversation with Dr Blackwood and Dr Shimmin except one about temperatures, after a visit from Dr Curnow Dr Blackwood and Dr Shimmin had told her to notify temperatures to them, and if the patient was fit to be moved they would see about it Temperatures were not to be charted unless they had seen the patient *first* Previously, any rise had been charted as it occurred in the normal way the record being transferred from the book to the chart by the junior sister the following morning After that conversation, if there was a rise the doctor was notified and would visit the patient next morning, and the nurses were told that if the patient had a temperature in the evening the doctors would notify the case The actual temperature was recorded in the temperature book by the staff nurse, sometimes in pencil and sometimes in ink After the conversation, the entry in the book was not transferred to the chart until the doctor had seen the patient If then the temperature was down, the previous rise was not charted She had instructed her nurses accordingly If the temperature rose the next day above 100 4° F, then the doctors usually transferred the case and the temperatures were put down correctly on the chart She could only remember one case that would have become certifiable under the Puerperal Pyrexia Regulations had the temperature been correctly recorded Three or four cases would have become notifiable under Dr Curnow's rules In one of Dr Shimmin's cases she had told the doctor that she would not take the responsibility of not notifying to Dr Curnow, in this case the chart had been correctly entered A second false chart had been prepared when the patient left on the 14th day, under Dr Shimmin's instructions, to send to County Hall The old, correct, one she had destroyed, on Dr Shimmin's instructions That was the only case she could remember

Cross-examined, she agreed that matron, assistant matron and sister tutor had been superior to her and that matron had visited every patient daily Matron had not inspected the temperature charts and books, but they had been available for her inspection The temperatures were only correctly reported to matron after the doctor had seen the patient, and all patients with temperatures were isolated If a temperature had been up the previous evening but was normal at the time of matron's round next morning matron would not be told of the evening rise, matron could have observed a blank on the chart, but in witness's experience she had never looked at charts If the temperature was up for the first time in the morning, matron would not be told of it until the doctor had been consulted The true temperatures would, however, be in the book where matron could see them if she asked It was true that in the only case she could remember the true temperature was recorded on the chart, and the falsification only arose when the patient had left hospital and a new, false chart was prepared for County Hall Dr Shimmin had taken some charts for County Hall instructing her to copy them as they were dirty, and told her to make out fresh charts which would indicate that this patient was non-notifiable, whereas the original charts showed notifiable temperatures She destroyed the originals although she had refused, as a certified midwife, to take the responsibility of not notifying them and had asked Dr Shimmin to take them to County Hall If a high temperature was repeated the patient was sent to Truro, so that in fact the regulations had been completely fulfilled The patient was always isolated as soon as a temperature rose, if the rise continued overnight (i.e. to 6 A M), so that any visitor could see the empty bed and deduce isolation and temperature, though the chart would not actually show a temperature reading Matron had left it to sister to notify the doctor of such cases The conversation with the doctors was soon after war broke out and she was not very clear about it, but she was positive both doctors were there The subject had been a patient of Dr Shimmin's who was running a temperature On the previous day Dr Curnow had been there and had found a chart and asked why the patient had not been sent to Truro Dr Blackwood had not regarded the case as one of puerperal fever Both doctors had said that no patient should be sent away until they had made investigations She had been told to contravene Dr Curnow's rules but not the statutory regulations —Dr Curnow's rule was that a single temperature of 99 4° F must involve immediate isolation and removal to Truro

Re-examined, she said she could not remember any case in which a temperature had been wrongly entered and the only effect of the doctor's instructions was to postpone the entry on the chart until the doctor had seen the case and made investigations She had told Sister Davies of the conversation with the doctors Her instructions had been to falsify the chart if the patient was notifiable under Dr Curnow's rules but not if notifiable under the regulations

* * *

Miss Esther Davies, state-registered nurse and certified midwife, said she had been employed at the Redruth Hospital from September, 1939, to June, 1941, succeeding Miss Commerford as sister in charge of the maternity ward She said that a single rise to 99 4° F in the evening was not charted unless it had fallen to normal next morning, if it did not fall, the doctor was told and if he did not think it necessary to notify "we just put another temperature down" She could not remember a single case in which she herself had ever falsified an entry She knew of one case where Sister Commerford had entered a false reading but did not remember the patient's name and thought she had had nothing to do with it She also had told Sister Love to make false entries in the cases of Mrs White and Mrs Carr She had never had any conversation with the doctors about it, except with Dr Blackwood about these two cases She had pointed out the temperatures to him, but could not remember what he said If the correct temperatures had been charted these cases would have been notifiable to Dr Curnow under his rules

Cross-examined, she agreed that her only reason for thinking Dr Blackwood had decided not to notify these cases was that in fact the patients had not been sent away She had not seen Sister Love enter an incorrect temperature, or alter the temperature book The real temperatures had been put in the books at first but she had on her own responsibility ordered that the books be altered to coincide with the charts There was no evidence at all of what the temperatures had really been Her recollection was that the temperatures had never been notifiable under the Puerperal Pyrexia Regulations

* * *

Miss Ena Love, state-registered nurse and certified midwife, said she had been on the staff of the Redruth Hospital as junior ward sister in the maternity ward from September, 1939, to August, 1941 She had taken temperatures and entered them in the book, the charts were never marked until next morning A wrong entry was made on the chart if a patient twice recorded 99 4° F and there seemed to be nothing wrong with her, the second reading was not then charted but a lower figure was substituted She had been so instructed by Sister Davies She had never had any conversation with the doctors about this matter She knew that a wrong temperature had been entered in the case of Mrs Carr She thought probably about three wrong entries in all had been made Mrs Cornish had been Dr Shimmin's patient and witness had reported to him daily on the condition She wanted Mrs Cornish to

Further cases are at present under investigation —Captain Taylor Have particulars of these cases been reported to the General Medical Council ?—Mr Bevin No, I think they have been investigated by the police —Sir Henry Morris Jones In the interests of the medical profession itself will the Minister adopt ruthless measures in the case of anyone found guilty of this type of allegation ?—Mr Bevin I certainly will, but I have to get evidence before I can bring a prosecution Doctors are very fortunate, they can bury their mistakes (laughter) —Captain Taylor Surely, if there have been eight or nine cases in respect of a particular doctor, that is sufficient evidence for a prosecution —Mr R de la Bere The thing is a scandal and needs cleaning up —Captain Taylor gave notice that in view of the unsatisfactory nature of the reply he would raise the matter again at an early date

Birth Registration and Ration Books

Mr A C Bossom asked the Minister of Health if he would see that the registration of newborn babies might be effected, in cases where the father was away on service and the mother could not attend, due to serious illness, by a responsible person equipped with the necessary medical certificates, making the application so that the essential ration book might be obtained —Mr Brown replied While birth registration is governed by statutory conditions which cannot and ought not to be disregarded, we recognise that unavoidable delay in birth registration must not be allowed to prejudice the mother and child in regard to essential food rationing facilities The Minister of Food and I are in touch about the matter

Maternal Mortality in Scotland

Mrs. A Hardie asked the Secretary of State for Scotland if any steps were being taken to provide more hospital accommodation for maternity cases, in view of the increase in maternal mortality in Scotland —Mr T Johnston replied In the past two years nearly 500 new maternity hospital beds have been made available Nearly 100 further beds will shortly be provided in buildings at present in course of erection I am advised, however, that shortage of beds is not a significant factor in the increase in maternal mortality

Infant Death-rate in Scotland

Mr T Kennedy asked the Minister if his attention had been drawn to the dangerously high stillbirth and neonatal death rate in Scotland , and if, in view of the fact that this high mortality and falling birth rate indicated need of an all-round improvement in medical, nursing and the general economic conditions of expectant mothers and growing children, including a widespread extension of communal dinners he could indicate the prospect of legislation to deal with the problem —Mr Johnston replied Stillbirths are not increasing, but a slight rise in neonatal deaths has occurred in 1941 It is too early to say whether the rise is temporary or not, but everything possible is being done by the Ministry of Food and the health authorities, central and local, to ensure that the nutritional needs of expectant mothers are met

School Meals in Scotland

Thirty one education authorities in Scotland supply solid meals in school, and the remaining four light meals, to children who are not necessitous (Mr Johnston in reply to Mrs Hardie)

Physical Standard for Ex-miners

In answer to a question Mr Bevin said The physical standard laid down for ex miners returning to the pits for underground work is that examiners should be satisfied that a man's general physique is such as to enable him to undertake work at or near the coal face , examiners are asked to give special attention to cases where valvular disease of the heart may be suspected Men are to be rejected if found to be suffering from tuberculous disease or uncontrollable hernia I have no information as to the number of men who are on an average passed as physically fit per hour Doctors are paid a fee of 5s for each man examined

Industrial Rehabilitation

The provisions of the interim industrial rehabilitation scheme extend to persons who are prevented by industrial disease, or tuberculosis, from following their normal occupation and who are suitable for training and employment in the occupations covered by the scheme (Mr Bevin replying to Mr F Messer)

Workers from Ireland

Mr W W Wakefield asked the Minister of Health if a medical examination was made of workers coming across from Ireland to ensure that they were not suffering from any disease —Mr Brown replied I understand from the Minister of Labour that there is no regular system of medical examination for workers coming to Great Britain from Eire or Northern Ireland, but that some are medically examined in their home areas at the instance of the employers engaging them I would refer to my reply on Nov 20 —Mr Wakefield Is the Minister aware that some workmen coming from Ireland may have tuberculosis, venereal disease and other diseases, and will he take steps to see that a proper examination is made at the port of entry in order to prevent these diseases from spreading in this country ?—Mr Brown Perhaps you will look at my answer (*Lancet*, Nov 29, p 681) —Sir Percy Hurd Is anything further being done following on that answer ?—Mr Brown The authorities have power to take certain action in regard to those diseases —Sir Joseph Nall Does the Minister realise that the matter is one of urgency and ought to be dealt with firmly ?—Mr Brown It is not merely a matter of these particular persons Preventive measures have to be applied in other directions too

---

SOCIAL SECURITY IN NEW ZEALAND

The N Z Government's second attempt to bring in a universal G P service which began on Nov 1 is a fee-for-service plan, the capitation system of February, 1941, having failed to take on My last note (see *Lancet*, Nov 15, p 615), writes a correspondent, described the medical and public outcry which resulted in the fee for a G P service being raised from 5*s* to 7*s* 6*d* with 12*s* 6*d* for an urgent or Sunday call Patients are allowed to make their own private arrangements if they wish and a doctor may charge 10*s* 6*d* or more Legally, however, he can sue for no more than 7*s* 6*d* , and this provision led the B M A to refrain from sending representatives to the committee of control, until this " ancient British right of access to court " be restored The B M A disapproves of the scheme but has agreed to work it, at the same time calling for a non-political commission of inquiry into the whole field The Government allow two methods of collecting the 7*s* 6*d*

(1) The patient signs a form to the effect that the service has been rendered The doctor sends in a heap of forms once or twice a month and is paid by the department

(2) The doctor bills his patient 10*s* 6*d* or whatever he chooses, and the patient's receipt is a valid claim at a post office for 7*s* 6*d* for each service

The B M A , fearing that in the future the 7*s* 6*d* might be cut down to 5*s* or 2*s* 6*d* , decided that its members should use method (2) , the patient and not the doctor would then be the loser Accordingly from Nov 1 practice will be carried on as usual, patients being assisted by the department in granting a 7*s* 6*d* rebate for each service A number of doctors, however, prefer method (1) on account of its simplicity and economy (of stamps paper, postage, time, &c especially in war time), and because many patients will regard the 7*s* 6*d* as a fair fee and will refuse to pay more No-one knows whether a specialist can charge 7*s* 6*d* for a poor patient, a follow-up examination after operation, or a cancer case These and many other points remain to be cleared up The scheme is expected to cost the Government £2,000,000 a year, which is a lot of money—especially if no great benefit to the people accrues

---

Joint Tuberculosis Council —Twenty members were present at a meeting of the council held at the London School of Hygiene on Nov 22 when Dr D A Powell (Wales) welcomed Dr J Ferguson (Surrey) representing the Society of M O H's and Dr G B Dixon (Birmingham) the National Association for the Prevention of Tuberculosis Dr Powell was nominated chairman for 1942, Dr James Watt (Godalming) and Dr Edward Ward (Devon) vice chairmen, Dr G Jessel (Lancs) treasurer, and Dr J B McDougall (Preston Hall) secretary For the care and rehabilitation committee Dr McDougall and Dr F R G Heaf stated that part 1 of the report dealing with rehabilitation would be published forthwith and part 2 on care committees early in the New Year Dr McDougall pointed out that the Ministry of Labour " interim scheme " could not apply to persons suffering from tuberculosis unless there was the closest coöperation between tuberculosis physicians and the ministry's visitor to the hospitals concerned Admission to the training centres of patients with open disease might have grave consequences its members to enter into and support the Government that while planning for war, also planned "for peace and a new society and thus, railways, the coal industry and substantial parts of arms production should be made national services during the war, and the public regulation of finance should be strengthened and consolidated" Mr Attlee's words in Parliament in May 1940 when almost absolute powers were taken over "persons and property" were also quoted Mr Attlee had said "The essential thing is that over a wide field—how wide one cannot say at the moment—industry will be carried on for the community in fact, and not for private profit" The case for a speedy unification of transport on national lines with state ownership and control was unanswerable This applied also to the coal industry The organisation proposed for the munitions industries was a special regional organisation with boards representing Government, technical and administrative staffs, and representatives of the workers with full power to organise and supervise in their respective districts Mr Shinwell ended "The Prime Minister promised the nation a harder time That we shall accept with fortitude, but we make this demand Those hardships must be borne by all alike Unless this is achieved it will stimulate further criticism and indeed opposition which may prove fatal to the Government's retention of office and, what is of infinitely greater importance, to our prospects of victory"

* * *

There is in this debate no immediate prospect of a complete change of Government, although some changes of individuals may take place But this active criticism is healthy and useful National unity does not imply absence of criticism and indeed in every other Parliament in the Dominions overseas there is more criticism because ordinary party government continues And we shall probably have a good deal more criticism in the second reading of the National Service (No 2) Bill And there will be more criticism of the allowances for service dependants—which are to be discussed again—and on health questions, for which a day may be found before Christmas The medical man-power problem has not yet been solved although investigations by the Shakespeare committee go on But this committee is a purely ad hoc fact-finding committee, excellent for the purpose, but when that is concluded it should dissolve To attempt to keep the Shakespeare committee in existence as an executive body to allocate medical man-power or to act as a court of appeal would be unfortunate There is no reason to superimpose an extra organisation on the present medical one, which, if used, is adequate

FROM THE PRESS GALLERY

Our Best Foot Foremost

When the Prime Minister moved a resolution in the House of Commons on Dec 2 that to secure the maximum national war effort the obligation of men and women for national service must be extended he assured members that though the Government proposals would further curtail the amenities of our lives they would not "affect physical health, or the contentment of spirit that comes from serving great causes"

In outlining briefly the bill he said there were three main changes affecting men block reservation would give way to individual deferment, the age for compulsory military service would be raised to 51 and lowered to 18½ Boys and girls between the ages of 16–18 will register and be interviewed by the youth committees of education authorities who will encourage them to join one of the various youth organisations Broaching the conscription of women Mr Churchill hastily said that compulsion to join the services would not be extended to any married women, even those without children The power to direct them into industry would continue but would be used with discretion General powers to conscript unmarried women would be sought but would probably only be applied to those in the age-group 20–30 who could choose between the A T S, civil defence work or industry Those who join the A T S will not be compelled to serve in the lethal or combatant branches

Mr James Griffiths pleaded that the Ministry should accept full obligation for those older men veterans of the last war, who might break down in health after being admitted to the Services

Mrs A Hardie, a Glasgow Labour member the principle that women should be drafted into of national importance but claimed that war was woman's job and she was not suited to barra Mrs M Tate on the other hand, felt that the was up against such appalling odds that women not keep out of war, but she regretted the lack wisdom shown in handling the woman-power Absenteeism in the factories, for instance was mainly to the disgraceful inadequacy of the number nursery schools and day-nurseries in the industrial Mr Ernest Bevin, as the last speaker in the debate took up the cudgels for the Government doughty fashion He admitted they were not with the amenities for the women's auxiliar but he was meeting the Service Ministers with a to improving them, and he mentioned specially pri and medical attention The present arr by which women doctors served on medical boards when women were examined would be extended so that women doctors might be in attendance to take care of the women called up

* * *

Just for a handful of silver he left us
Just for a ribbon to stick in his coat

In the debate in the Lords on Dec 3 on the organisation of man- and woman-power Lord Greville said that for some time hospitals had been fast losing their clerical and domestic staffs, who were attracted by the higher wages offered elsewhere or by a feeling that they wished to get into uniform He thought the hospitals would be able to retain many of them if they had some sort of uniform to wear True they had been offered a button, but he did not think a button was a very good substitute He wondered whether it could be arranged for girls who leave the hospital to join the A T S to return to the hospitals after enlisting if they are willing to continue with that kind of work

QUESTION TIME

Panel Doctors' Fees

Sir Ernest Graham Little asked the Minister of Health whether he was aware that panel practitioners had not received any increase in remuneration during the first two and a quarter years of war, that the proposed increase at the rate of 9*d* per annum, the first instalment of which, 2¼*d*, was payable on April 2, 1942, was inadequate to meet the increased expenses of practice, the higher cost of living, and the loss of private patients in receipt of incomes of £225 to £420 per annum, and whether he would make the increase more nearly approximate to the 2*s* asked for by the medical profession —Mr E Brown replied The increase in the capitation fee, which has been agreed with the representatives of the profession, will operate from the beginning of next year This increase is not intended to compensate doctors for the increase in the cost of living since other classes of persons earning similar incomes do not receive any bonus on this account I am satisfied, however, that it provides adequately for the other two matters mentioned in the question and I am not prepared to grant any further increase under present conditions

Reinstatement of Doctors

Mr T E Groves asked the Minister whether, in view of the recommendation to local authorities and hospitals that British doctors on their staffs might be released and foreign practitioners employed in their stead, he would give an undertaking that after the war the British doctors would be reinstated —Mr Brown replied The position of the British doctors referred to is safeguarded by the fact that the Defence Regulation under which practitioners with foreign qualifications are registered in the Medical Register will cease to operate when the Emergency Powers (Defence) Act, 1939, expires after the war

Alleged Incorrect Certificates

Captain Charles Taylor asked the Minister of Labour to what extent he had evidence that members of the medical profession had provided incorrect medical certificates to men of military age, stating that they were unfit for military service, and whether there had been any cases of the men concerned admitting that these certificates were untrue and obtained for large sums of money —Mr Ernest Bevin replied The police authorities investigated a number of cases last year but the evidence was not sufficient for a prosecution legs and forearms, but a few on each flank. The Wassermann and Widal tests were negative and a blood count was normal There was no history of tuberculosis in any near relative The temperature remained normal from Oct 23

The resemblance of the skin lesions to those described by Stott and Copeman[1] led me to start treatment with sulphapyridine Four 0 5 g tablets of M & B 693 were given at once, followed by three after three hours and thereafter two every four hours until 23 tablets were taken, representing 11 5 g of sulphapyridine The result was dramatic After 24 hours the spots were fading and no fresh crops appeared The spots disappeared uniformly and the most recent were arrested in their development, though after 48 hours their nodular character could still be felt The area over the lower third of the right tibia was now considerably less tender and swollen Six days after the beginning of treatment the skin lesions had all almost disappeared The patient vomited only once during the whole course of treatment After the sulphapyridine was stopped her appetite improved rapidly with her general condition At this stage she slept for unusually long periods each day and this tendency lasted for about a week Her progress since then has been continuous and uneventful

This seems to be a case of chronic meningococcal septicæmia without any evidence of involvement of the meninges

Finchley J GRIMSON

CONVALESCENT HOMES FOR CIVIL DEFENCE WORKERS

SIR,—May I draw the attention of your readers to facilities that are open to civil-defence workers through the Civil Defence Workers' Rest Department of the Joint War Organisation? Accommodation is available, in three Joint War Organisation convalescent homes near London which have been temporarily allocated for this purpose to civil-defence workers of both sexes in the Metropolitan area and Outer Ring who are in need of change after illness or injury or of rest and recuperation as a result of a long spell of duty, &c There is no charge to applicants, who may apply on their own account or through their A R P authority, in which case the applicant is asked to attend the weekly Red Cross medical inspection bringing a certificate from their own doctor and a leave permit from their A R P authority Civil-defence workers who have been hospital patients (either in- or out-patients) may proceed direct on application by the lady almoner to the Civil Defence Workers' Rest Department In addition to full-time civil-defence workers the facilities are at present also open to part-time A R P personnel, registered fire-watchers injured on duty, and those who have been discharged from the service but who contracted their illness or injury while in the service Free transport from central London is provided Accommodation is also available in the Bristol area for local personnel and it is hoped shortly to extend to other parts of the country Applications and requests for further information should be made to the secretary, Convalescent Section 6 Cadogan Square, S W 1 (Slo 9951)

HORDER
Chairman Civil-Defence Workers' Rest Dept J W O

TREATMENT OF THE MENOPAUSE

SIR,—Here comes that bogy-man again! This time in the guise of your own distinguished and authoritative self One tends to accept opinions uttered in your annotations as coming from eminent authorities on their subject and to take special note of any warnings thus expressed Coming from such a source a commentary on the treatment of the menopause cannot be lightly disregarded What do we find, then are the views expressed in your annotation of Dec 6 (p 705)? A warning against the use of stilbœstrol—" other œstrogens " are mentioned only in the last sentence—in the alleviation of menopausal symptoms the only crime that stilbœstrol—as compared with the other œstrogens apparently—has committed is to be " cheap and simple to take " and to yield in many cases dramatic results In sounding this warning you quote only one reference (*Amer J. Obstet Gynec* 1940, 40 980), a paper by a psychiatrist whose evidence is based on the use of stilbœstrol which he describes as " a new synthetic ovarian follicular hormone not yet available for general use " in 26 cases of psychosis, including involutional melancholia, schizophrenia and Korsakoff's syndrome, occurring in the menopausal era or subsequent to it This is the first time I have heard of œstrogens as a cure for secret drinking in elderly women None of the patients complained of hot flushes In spite of the fact that " the amounts of the synthetic hormone prescribed were considerably in excess of any as yet reported in the literature " the psychiatric clinical course during treatment showed no improvement in 67% and ' 4% became much worse " You will note that 4% of 26 patients is roughly 1 patient However, as is not altogether surprising in view of the somewhat alarming size of the dose which must have been given—the original author does not bother to mention the exact doses—certain symptoms and effects did appear Here you assume too faithfully the rôle of reporter at the expense of your critical functions and mention " other toxic side effects such as enlargement and fullness of the breasts, areolar pigmentation, increased sexual feelings nausea, diarrhœa and even dysmenorrhœa ' These effects are said by the author to be due to stimulation of ovarian and genital activity by stilbœstrol It is certainly interesting to hear a psychiatrist describe increased sexual feelings as a toxic side effect! Œstrogens of course, far from stimulating ovarian activity actually depress it

But not content with these warnings your annotation resurrects two favourite old bogies and introduces a new one which I find fascinating and intriguing Here they are " No actual evidence is clinically available that this substance is in man a carcinogen, yet no-one would sponsor its exhibition in a case of established breast or uterine cancer " This matter has been fully discussed in many places, including your own columns (e g , *Lancet*, 1936, 2, 1365) Cramer and Gye showed that prolonged administration of œstrogen in high doses was capable of causing mammary cancer in susceptible strains of mice, but pointed out that the period of administration necessary to produce such carcinoma in mice would correspond in terms of the human life cycle to 7–10 years There is even less evidence of the induction of malignant tumours of the uterus in experimental animals Secondly, your annotation mentions the occurrence of pituitary tumours in small animals after the administration of œstrogens Nothing of the kind has so far been reported in human beings, though œstrogens have now been used extensively for 10 years Finally, it makes the fascinating suggestion that " some patients seem to acquire almost a drug addiction to stilbœstrol " and are difficult to wean from its subtle attraction I know of no evidence to suggest that stilbœstrol or any other œstrogen induces a drug addiction, though I have seen patients whose menopausal symptoms are relieved by œstrogens loath to discontinue what they conceive to be an efficacious form of therapy !

Your annotation is entitled Treatment of the Menopause Treatment of the menopause with œstrogens consists in the administration of small doses in interrupted courses controlled when possible by vaginal smears and hot-flush counts, and not in giving maximal doses to psychotic patients of menopausal or post-menopausal age showing none of the recognised signs attributable to ovarian deficiency By the prudent use of œstrogens I can assure you that you will avoid what you describe as " toxic side effects " and may with an easy conscience abandon your rôle of bogy-man

Endocrine Clinic Guy's Hospital P M F BISHOP

STETHOSCOPES OLD AND NEW

SIR,—I should like to add a few remarks to the annotation in your issue of Nov 15 While the usual types of stethoscope rely on an air-space to act as sound-box, there are some in which the sound is transmitted without intermediate amplification directly by means of a solid conductor of wood ebonite or other plastic This type of stethoscope consists of a solid rod, one end of which is funnel-shaped and has a roughened surface to prevent it slipping on the skin while the other end fits tightly into an ear-piece similar to that of other stethoscopes The loss of amplification in this type is usually well compensated by the truth of transmission and the complete absence of extraneous sounds Moreover, the ordinary chest-piece must be applied firmly and the

Letters to the Editor

STILLBIRTH AND NEONATAL MORTALITY

SIR,—As Professor Baird and Dr. Wyper recognise, the numbers of cases analysed in their paper (*Lancet*, Nov. 29, p. 657) are small and must be accepted with reserve, but their findings are substantiated by a statistical study shortly to be published, which I have recently completed, and this covers an analysis of the trend in social mortality since 1911 by age, occupation of father, cause of death, regional incidence, and other factors. I find that although the difference between the highest and lowest economic groups has narrowed somewhat since 1911 for neonatal mortality (the excess having fallen to 66%), the difference at ages 1–3, 3–6 and 6–12 months has increased. Despite, therefore, the fall in the absolute death-rates, the excess shown by the lowest class over the top class at ages 6–12 months, for instance, rose from 299% in 1911 to 498% in 1930–32.

Baird and Wyper find that the neonatal mortality-rate for booked cases is 27·4 per 1000 (1938–40). This may be compared with the rates for Croydon (17 in 1938), large Dutch communes (17·7 in 1930–32), Oslo and Amsterdam (16 in 1936), doctors in England and Wales (20·5 in 1930–32), and class I England and Wales (21·7 in 1930–32), while even infants of bricklayers' labourers in England and Wales had achieved a rate (26·3) lower than that reported eight years later by Baird and Wyper for booked hospital experience. Moreover the neonatal death-rates for children born to civil servants, doctors, dentists, teachers and other analogous economic groups were lower thirty years ago than the corresponding rate for Aberdeen Hospital found by Baird and Wyper. These and many other facts go far, I suggest, to confirm their general conclusions on the need for immediate measures to be taken by the appropriate authorities.

Chiswick, W. 4. RICHARD M. TITMUSS.

PERFUMED HYPOCHLORITE SOLUTIONS FOR SPRAYING

SIR,—Some people object to the odour of the mist of sodium hypochlorite used in the disinfection of the air of air-raid shelters and other crowded or poorly ventilated spaces. This objection can be overcome, however, by treating the hypochlorite before spraying with a small quantity of a pleasant smelling substance. The choice of such a substance, together with any solvents that may be necessary to disperse it in the hypochlorite solution, is limited by the following conditions: (1) It must be resistant to the chemical action of sodium hypochlorite; (2) it must not impair the bactericidal action of the mist; and (3) it must not be toxic in the concentration necessary to provide an effective masking odour. It has been found that the two mixtures mentioned below fulfil these conditions:

	A	B
β naphthyl methyl ether (Neroli)	1 g	
Trinitro tertiary butyl xylene (synthetic musk)		1 g
Cetyl alcohol	1·5 g	1·5 g
Carbon tetrachloride	10 c.cm.	10 c.cm.
Sulphonated castor oil	15 c.cm.	15 c.cm.
Water to	100 c.cm.	100 c.cm.

If 1 c.cm. of either A or B is added to 100 c.cm. of 1% sodium hypochlorite a mist is produced on spraying in which the odour of hypochlorite is not discernible. The dispersion of the scent in hypochlorite is relatively stable in the physical sense but may if the solution is left still for several hours, tend to flocculate. Complete redispersion can be achieved by slight agitation. The chemical stability of the dispersion has been tested by leaving an excess of mixtures A and B in contact with 1% sodium hypochlorite solution for a week. No appreciable reduction of the available chlorine in the solution occurred. Similarly the bactericidal action of the perfumed hypochlorite was tested by spraying it in a sealed room into which a mist of *Streptococcus salivarius* in broth had previously been introduced; it was found that there had been no sensible diminution in the killing power of the hypochlorite.

Finally, in regard to the toxicity of the components of the two mixtures chosen. It should be noted that at the concentration of hypochlorite often recommended for use as an aerial disinfectant—i.e., to give 1 volume of hypochlorous acid in 2×10^6 volumes of air—the corresponding concentration of either scent is in the order of 1 volume in 5×10^8 volumes of air, at which concentration very few of even the most poisonous substances have any action when breathed over long periods. Similarly with the solvents and dispersing agents used, cetyl alcohol and sulphonated castor oil are almost non-poisonous in themselves, and carbon tetrachloride quite harmless in the very small concentration used. In point of fact, Davis in the *J. Amer. med. Ass.* 1934, **103**, 961, suggests that it is safe to work for long periods in a concentration of 1 part of carbon tetrachloride in 10^4 parts of air; the quantity which will be sprayed from the scented hypochlorite is 1 part in 3×10^7 which is less than a threethousandth of this safe maximum.

National Institute for Medical Research. O. M. LIDWELL.

PERINÆAL SUTURE UNDER LOCAL ANÆSTHESIA

SIR,—I am indebted to Prof. F. J. Browne for pointing out that he has been using for many years the technique I described (*J. Obstet. Gynæc.* 1941, 48, 610) for suturing the perinæum under local anæsthesia. I was not, of course, claiming any originality for the method, and I must apologise to Professor Browne for omitting reference to his article on the subject. War conditions made an exhaustive search of the literature difficult. I was aware that the method was in use in one or two hospitals but I did not know of any specific instances. My aim in writing the article was to make the method more generally popular, for the serious disadvantages and dangers of giving a general anæsthetic to a woman exhausted by the strain of labour are not sufficiently realised. Professor Browne's testimony to the value of the method will, I hope, help to popularise it. The cases I described were the first on which the method was used as a routine at Charing Cross Hospital. Since then, I believe, it has been regularly adopted.

Hendon. DENYS J. NEAL SMITH.

CHRONIC MENINGOCOCCAL SEPTICÆMIA

SIR,—The following case seen in general practice seems similar to those described by Major Dickson and others in the *Lancet* of Nov. 22.

A lady in middle life had been in good health up to about six months before the present illness. During this period she had become more easily tired and disinclined to do her normal duties. In the evening of Oct. 17, 1941, she had a definite rigor. She sweated profusely during that night and spent the next day in bed. On the 19th red spots appeared on the lower parts of her legs, round the ankles and on her wrists and forearms. The spots were neither painful nor itchy, and she said that if she had not seen them she would not have been aware of their presence. On the 20th she dressed and went downstairs, feeling "very seedy." I was called to see her on the 22nd. She was then in bed. Her chief complaint was a feeling of extreme weakness and a tendency to faint when she got out of bed. She then drew my attention to the spots on her legs and arms. She looked pale, her temperature was 99° F. and pulse-rate 72. The tongue was clean and moist, and the throat slightly reddened. There were no enlarged glands and I found no abnormality in the heart, lungs, C.N.S. or abdomen. There was a crop of round pink spots on the dorsum of both feet, on the lower third of the front of both legs, on the backs of the hands, and on the forearms. There were a few isolated spots on the flanks and one in the right scapular area. The spots resembled those of erythema nodosum but with three major differences—they were all of uniform size and shape, and each spot was about the size of a split pea; some of the older lesions had a minute hæmorrhagic centre; and they were neither itchy nor painful. The patient told me that a few fresh spots appeared each day. They were appreciably raised above the skin surface; on pressure they were slightly tender but did not disappear. Over the lower third of the right tibia there was an area of subcutaneous swelling. This pitted on pressure and was tender, but there was no discoloration of the overlying skin, except in the areas where the spots were situated. There were no joint pains, the patient did not complain of headache, and Kernig's sign was absent. During the following days fresh crops of spots appeared, all on the lower parts of the legs and forearms, but a few on each flank The Wassermann and Widal tests were negative and a blood count was normal There was no history of tuberculosis in any near relative The temperature remained normal from Oct 23

The resemblance of the skin lesions to those described by Stott and Copeman[1] led me to start treatment with sulphapyridine Four 0 5 g tablets of M & B 693 were given at once, followed by three after three hours and thereafter two every four hours until 23 tablets were taken, representing 11 5 g of sulphapyridine The result was dramatic After 24 hours the spots were fading and no fresh crops appeared The spots disappeared uniformly and the most recent were arrested in their development, though after 48 hours their nodular character could still be felt The area over the lower third of the right tibia was now considerably less tender and swollen Six days after the beginning of treatment the skin lesions had all almost disappeared The patient vomited only once during the whole course of treatment After the sulphapyridine was stopped her appetite improved rapidly with her general condition At this stage she slept for unusually long periods each day and this tendency lasted for about a week Her progress since then has been continuous and uneventful

This seems to be a case of chronic meningococcal septicæmia without any evidence of involvement of the meninges

Finchley J **GRIMSON**

CONVALESCENT HOMES FOR CIVIL DEFENCE WORKERS

SIR,—May I draw the attention of your readers to facilities that are open to civil-defence workers through the Civil Defence Workers' Rest Department of the Joint War Organisation? Accommodation is available, in three Joint War Organisation convalescent homes near London which have been temporarily allocated for this purpose to civil-defence workers of both sexes in the Metropolitan area and Outer Ring who are in need of change after illness or injury, or of rest and recuperation as a result of a long spell of duty, &c There is no charge to applicants, who may apply on their own account or through their A R P authority, in which case the applicant is asked to attend the weekly Red Cross medical inspection bringing a certificate from their own doctor and a leave permit from their A R P authority Civil-defence workers who have been hospital patients (either in- or out-patients) may proceed direct on application by the lady almoner to the Civil Defence Workers' Rest Department In addition to full-time civil-defence workers, the facilities are at present also open to part-time A R P personnel, registered fire-watchers injured on duty, and those who have been discharged from the service but who contracted their illness or injury while in the service Free transport from central London is provided Accommodation is also available in the Bristol area for local personnel, and it is hoped shortly to extend to other parts of the country Applications and requests for further information should be made to the secretary, Convalescent Section, 6 Cadogan Square, S W 1 (Slo 9951)

HORDER,
Chairman, Civil-Defence Workers
Rest Dept , J W O

TREATMENT OF THE MENOPAUSE

SIR,—Here comes that bogy-man again! This time in the guise of your own distinguished and authoritative self One tends to accept opinions uttered in your annotations as coming from eminent authorities on their subject and to take special note of any warnings thus expressed Coming from such a source a commentary on the treatment of the menopause cannot be lightly disregarded What do we find, then are the views expressed in your annotation of Dec 6 (p 705)? A warning against the use of stilbœstrol—" other œstrogens " are mentioned only in the last sentence—in the alleviation of menopausal symptoms the only crime that stilbœstrol—as compared with the other œstrogens apparently—has committed is to be " cheap and simple to take " and to yield in many cases dramatic results In sounding this warning you quote only one reference (*Amer J Obstet Gynec* 1940, 40, 980), a paper by a psychiatrist whose evidence is based on the use of stilbœstrol which he describes as " a new synthetic ovarian follicular hormone not yet available for gener use," in 26 cases of psychosis, including involution melancholia, schizophrenia and Korsakoff's syndrom occurring in the menopausal era or subsequent to This is the first time I have heard of œstrogens as cure for secret drinking in elderly women None of t patients complained of hot flushes In spite of the fa that " the amounts of the synthetic hormone prescrib were considerably in excess of any as yet reported in t literature " the psychiatric clinical course during trea ment showed no improvement in 67% and " 4% becar much worse " You will note that 4% of 26 patients roughly 1 patient However as is not altogeth surprising in view of the somewhat alarming size of t dose which must have been given—the original auth does not bother to mention the exact doses—certa symptoms and effects did appear Here you assume t faithfully the rôle of reporter at the expense of yo critical functions, and mention " other toxic side effec such as enlargement and fullness of the breasts, areol pigmentation, increased sexual feelings nausea, diarrho and even dysmenorrhœa " These effects are said b the author to be due to stimulation of ovarian a genital activity by stilbœstrol It is certainly interesti to hear a psychiatrist describe increased sexual feelin as a toxic side effect ! Œstrogens, of course, far fro stimulating ovarian activity actually depress it

But not content with these warnings your annotati resurrects two favourite old bogies and introduces a ne one which I find fascinating and intriguing Here th are " No actual evidence is clinically available th this substance is in man a carcinogen, yet no-one wou sponsor its exhibition in a case of established breast uterine cancer " This matter has been fully discuss in many places, including your own columns (e g *Lancet*, 1936, 2, 1365) Cramer and Gye showed th prolonged administration of œstrogen in high doses w capable of causing mammary cancer in susceptib strains of mice, but pointed out that the period administration necessary to produce such carcinoma mice would correspond in terms of the human life cyc to 7–10 years There is even less evidence of t induction of malignant tumours of the uterus in expe mental animals Secondly, your annotation mentio the occurrence of pituitary tumours in small anima after the administration of œstrogens Nothing of t kind has so far been reported in human beings, thoug œstrogens have now been used extensively for 10 yea Finally, it makes the fascinating suggestion that " son patients seem to acquire almost a drug addiction stilbœstrol " and are difficult to wean from its subt attraction I know of no evidence to suggest th stilbœstrol or any other œstrogen induces a drug addi tion, though I have seen patients whose menopaus symptoms are relieved by œstrogens loath to discontin what they conceive to be an efficacious form of therap

Your annotation is entitled Treatment of the Men pause Treatment of the menopause with œstroge consists in the administration of small doses in inte rupted courses controlled when possible by vagin smears and hot-flush counts, and not in giving maxim doses to psychotic patients of menopausal or pos menopausal age showing none of the recognised sig attributable to ovarian deficiency By the prudent u of œstrogens I can assure you that you will avoid wh you describe as " toxic side effects " and may with a easy conscience abandon your rôle of bogy-man

Endocrine Clinic Guy's Hospital P M F **BISHOP**

STETHOSCOPES OLD AND NEW

SIR,—I should like to add a few remarks to t annotation in your issue of Nov 15 While the usu types of stethoscope rely on an air-space to act as soun box, there are some in which the sound is transmitte without intermediate amplification directly by means of solid conductor of wood, ebonite or other plastic Th type of stethoscope consists of a solid rod, one end which is funnel-shaped and has a roughened surface prevent it slipping on the skin while the other end fi tightly into an ear-piece similar to that of other steth scopes The loss of amplification in this type is usual well compensated by the truth of transmission and t complete absence of extraneous sounds Moreover, t ordinary chest-piece must be applied firmly and t pressure exerted influences the quality of the transmission, whereas the solid conductor type relies on point contact only and can be applied in almost any way Thus it has great advantages for teaching because the distortions and extraneous sounds arising from inexperienced use of the other types are completely absent and the beginner can easily distinguish the true heart-sounds The close approach to the patient which the use of this instrument necessitates may, however, be inconvenient for the examiner

---

[1] *Lancet*, 1940 1 1116

London W 1 J PLESCH

A CONTRAST

SIR,—The *Times* on Dec 5 reported that the Duke of Kent visiting the Nursing Recruitment Centre spoke of the " fine career " now offered by nursing and added that he could speak " with personal knowledge of the excellent conditions in the hospitals today "

The *Royal Cornwall Gazette* on Nov 1 reported an inquest held on a baby who had died in a public-assistance hospital The autopsy had shown death to be due to suffocation through the child inhaling its own vomit The coroner's comments included these words " I have called you together because you may feel it your duty to comment on the member of the staff at the hospital There are about 80 patients at present and we shall hear that neither of the two young nurses on night duty is qualified nor trained " In her evidence the nurse involved stated that she had to start washing patients at 3 30 A M make the beds of 33 patients, give the inmates their first morning feed and assist with the breakfast She added that she had to visit ten separate wards, five on the bottom floor and five on the top floor It was stated that of the nursing staff of eight only the sister-in-charge was trained

Can one blame parents who hold back their daughters from the " fine career " of nursing if they are liable to be confronted with conditions such as the above during their so-called " training " ?

Northwood ESTHER CARLING

LUPUS ERYTHEMATOSUS AND TUBERCULIN TESTS

SIR,—Some points in Dr Kelvin's article of Nov 15 require further elucidation He found that 71% of 118 cases of lupus erythematosus gave a positive tuberculin reaction as compared with 18% of 240 adult controls This latter figure is extraordinarily low when compared with other mass tuberculin surveys In 1929 D'Arcy Hart, on testing 751 clinically non-tuberculous controls of all ages, found that in the adult age-group 88% were positive to 1 in 1000 tuberculin Admittedly these figures relate to the highly industrialised district of London and probably a slightly lower figure would be obtained if this survey were repeated now It would be of interest to know from what section of the populace Dr Kelvin's controls were derived, whether urban or rural, and how this very low figure of 18% can be accounted for when compared with the findings of other observers It is also stated in the article that a tuberculous history was commoner among the cases of lupus erythematosus than among the controls This statement would be more convincing if the actual figures relating to this were given I am not qualified to express any opinion as to the ætiology of lupus erythematosus but I feel that some explanation of the points I have raised is necessary before the author's conclusions can be accepted

Colindale Hospital, N W W E SNELL

SIR,—I am prepared to believe that in Dr Kelvin's area the tuberculous cases of lupus erythematosus are commoner than in the south of England This was a point I emphasised in a recent paper But how does he account for the numerous published cases of the acute generalised form of the disease which ended fatally and in which either no trace of tuberculosis or no active focus was found post mortem (e g , Roxburgh, A C *Brit J Derm* 1933, 45, 95)? In such cases there must be a flooding of the blood-stream with toxin Most of them, of course, die of streptococcal septicæmia (all of Roxburgh's five cases) Forman and I in 1933 published a paper (*Ibid*, p 4) on intradermal tests in lupus erythematosus and allied conditions and our results were very different

London, W 1

Obituary

THOMAS HENRY WILSON

M A DUBL , F R C P I

Dr T Henry Wilson, a former president of the Royal College of Physicians of Ireland and King's professor of midwifery in the school of physic, Trinity College, died on Nov 20 at the age of seventy-six Wilson was the elder son of the late Captain John Wilson of XIV Regiment, and was educated at Foyle College, Londonderry, and at Shrewsbury He qualified in 1887, and spent some time as a ship surgeon When he came home he turned to midwifery and was assistant master at the Rotunda Hospital for three years during Sir William Smyly's mastership Later he was appointed gynæcologist to the Richmond Hospital and to Sir Patrick Dun's Hospital, and in 1898 he became F R C P I and in 1926 was elected president He had been appointed to his chair in 1911 and he held this post till 1936 when ill health forced him to retire His widow, elder daughter of the late Colonel W Lyster Smythe, survives him

Wilson was a retiring man, who took little part in professional affairs As a teacher he was painstaking and courteous, and his skill as a surgeon won for him a good gynæcological practice He was a charming companion, and his friends found him kindly, humorous and tolerant

ALGERNON E L WEAR

C M G , M D DURH , D P H

Colonel Wear, who died last week at Harrogate in his 76th year, was born in Newcastle-on-Tyne and educated at the local grammar school After qualifying at Durham University in 1891 he held many residential posts in Leeds before settling there in general practice He became a part-time school medical officer and in 1910 his full-time appointment gave scope to remarkable organising abilities He had a great influence on his staff, whom he inspired with his own conception of school medicine, and the open-air school owes much to his wisdom and foresight His greatest fight was over cleanliness in which he achieved striking results Like many busy people he had many outside interests He joined the old volunteer corps before it became the R A M C for some time acting as adjutant When the Territorial Army was organised in 1908 Wear became the first commanding officer of the 1st West Riding field ambulance, which he raised to a high state of efficiency until he was put in command of the divisional casualty clearing station which he later took out to France as the 7th C C S remaining with it until he came home to take up an important command at Alnwick For his services he was made C M G and later became president of the Leeds branch of the " Old Contemptibles " He was largely responsible for the foundation of the Poor Children's Holiday Camp (with a record of summer holidays for 24,000 children) and was one of the pioneers of the orthopædic hospital at Kirby Moorside Two well-known Leeds institutions, the " Boots for Bairns " fund and " Children's Day," owed much to his efforts An engineer before he started medicine, Wear was a great model locomotive builder and had a magnificent model railway at one time He was a loyal freemason, and a past master of his lodge who never sought higher honours He married Emily, eldest daughter of the Rev F Peel, vicar of Heslington, York, and leaves her with two sons and two daughters

WILLIAM FORDYCE

M D EDIN F R C P E , F R C O G

Dr William Fordyce, who died at Tillicoultry, Clackmannan on Nov 6, at the age of 78, was the last of that group of brilliant obstetricians—Simpson, Croom Barbour Hart, Murray, Haultain Ferguson, and Lackie—who added to the renown of the Edinburgh school of medicine

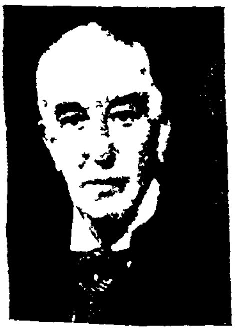
Though he was born at Liverpool, Fordyce counted himself a Fifer, for his parents came from the Kingdom and he himself was educated at Anstruther and later at St Andrews, where he read for an arts degree He studied medicine at Edinburgh, graduating with first-class honours in 1888, and five years later, after postgraduate study at Leipzig and Berlin, he took his M D

Once he had decided to specialise in obstetrics he was invited by Sir Alexander Simpson who was a close personal friend to become his assistant at the university and later he was appointed a lecturer in the extramural school He also held staff appointments at the Royal Maternity and Simpson Memorial Hospital, the Royal Infirmary Leith Hospital and the Hospital for Women in Archibald Place and soon he was recognised as one of the leading obstetricians and gynæcologists of Edinburgh He retired from the heavy demands of his private practice some ten years ago

Dr Fordyce served as president of the Edinburgh Obstetrical Society in 1919 Already in 1898 he had been elected to the fellowship of the Royal College of Physicians of Edinburgh, and in 1929 he became a foundation fellow of the new college of obstetricians Apart from these professional contacts he was a member of the Pen and Pencil Club, the Scottish Arts Club, and, as Father Profundus, of the Monks of St Giles C K writes Fordyce was a vivid and colourful teacher, a brilliant diagnostician and a skilful operator He was a man of many gifts and tastes—an average golfer a good curler, and an excellent angler He was also a witty versifier and a popular after-dinner speaker, and his songs and recitations told in his own inimitable way will live in the memory

GODFREY DE BEC TURTLE

M D DURH M R C P



Lafayette

Dr de Bec Turtle died on Dec 1 after a brief illness at the Luton and Dunstable Hospital which he had gone to superintend He will be much missed in and around Cambridge Square where he had been for some forty years the trusted family physician, retaining to the last the signs-manual of silk hat and stock He rose early and was a constant figure in the Row before breakfast with his friend Sir William Willcox, he could often be found at the Olympia horse show where he had been known to compete on one of his own excellent horses Always interested in everything around him sympathetic and helpful to a degree, he had a sound business head with which he served many professional occasions The Harveian Society came first, then the Royal Society of Medicine whose financial position brightened during his years of office, and when his experience had ripened he was invited to preside at the council of the Medical Defence Union, and four days before his death was elected chairman of the Medical Sickness Assurance Society And he was never happier than when he was giving a dinner party with his wife and family to medical men from home or abroad

Born at Woodford, Essex, in 1877, the son of Dr Frederick Turtle Godfrey de Bec Turtle was educated at Haileybury King's College, London, and Durham University, where he graduated with honours in 1902 Two years later he took his M D and in 1908 became M R C P While obtaining these higher qualifications he was strenuously preparing himself for his future work —later many colleagues were glad to come to him for counsel, especially in midwifery cases—and after holding resident appointments at King's he spent three years as R M O at the Public Dispensary, Drury Lane He never severed his connexion with this hospital and when he died was its senior physician He also found time to undertake clinical assistantships at the Evelina Hospital the Royal Eye Hospital and the Children's Hospital at Paddington Green, but he gave up this work when in 1911 he was appointed physician to the Margaret Street Hospital for Consumption Dr Turtle married Florence Cawood, daughter of Mr H H Baker, they had two daughters, and one son, Dr Peter Turtle, now serving as a surgeon commander

---

Major ARTHUR BRODIE HAMILTON BRIDGES, O B E, who died at Cheltenham on Oct 22 at the age of 55 after an operation, took his conjoint qualification from St Thomas's Hospital in 1912 and received his commission in the R A M C from the special reserve a year later During the last war he served in Gallipoli Macedonia and Egypt, and later in India he was appointed surgeon to the Commander in Chief After the war he served as surgeon captain to the Life Guards but returned to the R A M C in 1923 and was promoted major two years later He retired in 1933, but took up a retired pay appointment at the central recruiting depot in 1938

Medical News

University of Cambridge

On Dec 6 the following degrees were conferred by proxy —

M D—T D Day

M B, B Chir—R E M Pilcher and R E W B. Comerford

University of Manchester

At recent examinations the following were successful —

FINAL EXAMINATION FOR M B, CH B

J G Atherton, J K Brown, J H Hilditch, S H Jackson, Heskel Khazam, N A Lewtas, N S Marsden, Ann L Pinson, G J Shanklin and H G B Slack

University of Wales

At recent examinations for the degrees of M B, Ch B the following were successful —

Pathology and Bacteriology—E R Edmunds, Phœbe J M Griffiths, Tegwyn Jones, H D Walters and Al A Yauniskis

Surgery—Beryl Bevan, W M Jones and Monica Parry Morton

National University of Ireland

The degree of M D, has been conferred on Patrick FitzGerald and Dermot Roden

University of Dublin

At recent examinations at the school of physic, Trinity College, the following were successful —

M D

W M E Anderson, R S W Baker and M C Wood

FINAL EXAMINATION FOR M B B CH AND B A O

Medicine—L H Shrago J R Hassard and Dorothy H Webster (*second class honours*) Ethna M MacCarthy, L H Citron C E Williams Florella Starritt, J A Pearce J B Dunlop, Kathleen M J Morphy J N Greene, Muriel Eakins Basil Marcus, A R B Jackson, E S Odbert M. B Flanagan, R O D Reid T L Kelly, A C McReynolds, Margaret F Y Dixon and Catherine E Craig

Surgery—Emmeline P Crowe N J Anderson, L H Shrago Dorothy W M Last, J P Walsh, A J B MacFarland, Al C McReynolds, L H Citron, Jack Morris, and J A Pearce

Faculty of Radiologists

The following were successful at the examination for the fellowship of the faculty —

Radiodiagnosis—Eric Samuel, M D Lond F R C S, D M R E

Radiotherapy—Alice M Ross, M B Edin, F R C S E, D M R E

Royal Society of Medicine

The section of comparative medicine of this society will continue their discussion on the control of diseases of cattle inimical to man on Wednesday, Dec 17, at 2 15 P M, when Prof Thomas Dalling, M R C V S, and Dr S Roodhouse Gloyne will speak on tuberculosis On Dec 18 at 2 30 P M at the section of neurology Prof Geoffrey Jefferson, Prof Hugh Cairns, Dr W Russell Brain and Dr Ludwig Guttman will open a discussion on rehabilitation after injuries to the central nervous system

Strickland Goodall Lecture

The third Strickland Goodall lecture will be delivered at the Apothecaries Hall in June, 1942, by Dr William Evans, assistant physician to the cardiac department of the London Hospital His subject will be triple rhythm

Prevention of Accidents

The second training course for industrial accident prevention organisers to be held in this country has now been arranged by the Royal Society for the Prevention of Accidents on behalf of the factory department of the Ministry of Labour It will be held at Balliol College, Oxford, from Jan 2 to 13, and about 50 trainees, nominated by their employers, can be accommodated The programme may be obtained from the secretary of the society, 52, Grosvenor Gardens, London, S W 1

Notes, Comments and Abstracts

BADGE OF OFFICE

Sweeping and garnishing never had their due while our world still clung to the Victorian belief that you came down to breakfast at eight o clock and found the rooms clean and tidy, the fire burning and the coffee made, and that it was all done by magic Most of us have given up that any notion in private life but in hospitals the domestic work still has to be done, and done early, and there is not much magic about it We have already noted (*Lancet*, Nov 22, p 655) that the Ministry of Health, with genuine appreciation of the contribution which hospital domestic workers are making towards winning this war, have decided to provide badges for them More insight has been shown in making the gesture than in choosing the design of the badge (shown in the illustration) The words " Ministry of Health " appear in silver letters on a red enamelled border, and " Hospital Service " is in blue on a silvered cross-bar The effect though honest is dispiriting Might not one of our penniless artists have been given the opportunity to do a national service and design a badge worthy of the ministerial inspiration ?

Badges will be issued to all those workers on the domestic side in hospitals, including manual and supervisory staff, who are giving not less than 96 hours service a month, and it is estimated that 60,000 people will be eligible, most of them women Many hospitals are short of domestic workers, and the Ministry of Labour has agreed that women giving full-time service in this capacity will not be asked to transfer to other war work, moreover women who are not in essential employment can, if they wish ask to take up this work when they register No doubt the recognition of the value of the work which the badge implies will carry some weight with registrants

FELIX INFELIX

" limited quantities of damaged dried milk no longer suitable for human food can be issued to owners of warehouses and other food stores in which cats are kept to destroy vermin " (Hansard)

Milkless, my cat ? Observe the regulations
 You cannot hope to share the infant's meed
In time of war the milk becomes the nation's,
 And who are you to swig the nation's need ?
Yes, who indeed are you ? Cry out upon us !
 A personage of note, not all unsung
The harmless necessary cat, your honours—
 The milkless mouser with a parching tongue
Harmless and necessary ? What, no greater ?
 Doyen of symmetry, address, aplomb !
The saucer, yawning like an empty crater,
 Shows where the Minister has dropped his bomb
Someone, I think, remarked you had your uses,
 Major Lloyd George unblushingly replied
" The modicum of milk reserved for pussies
 Is damaged, dated, damned, disdained and dried "

FLASHBACK

A Diary of World Affairs by Marcel Hoden (Penguin Books 6*d*) which covers the period from June, 1940, to April, 1941, is a useful reminder of the sequence of events during a tumultuous year which to most people was too confusing to be seen in perspective. As a collection of facts as to who said and did what—and when—it is concise and readable Whether the author's optimistic interpretation of these events is as reliable only time will tell For a Frenchman disappointed in his own country's behaviour he seems a little too enthusiastic in his eulogy of ours Perhaps he ought to give up expecting too much of human nature, or disappointment may become his lasting portion

---

Burroughs Wellcome and Co inform us that, subject to priority demands, Tabloid sulphaguanidine 0 5 g is now available to the medical profession

Infectious Disease in England and Wales

WEEK ENDED NOV 29

Notifications —The following cases of infectious disease were notified during the week smallpox, 0, scarlet fever 1415, whooping-cough, 1959, diphtheria, 1047 paratyphoid, 16, typhoid, 7, measles (excluding rubella), 850, pneumonia (primary or influenzal), 1101 puerperal pyrexia, 124, cerebrospinal fever, 140, poliomyelitis, 15, polio-encephalitis, 1, encephalitis lethargica, 3, dysentery, 197, ophthalmia neonatorum 83 No case of cholera, plague or typhus fever was notified during the week

The number of civilian and service sick in the Infectious Hospitals of the London County Council on Nov 26 was 1319, including scarlet fever, 168 diphtheria, 287 measles, 36, whooping-cough 481, enteritis, 32, chicken pox, 36 erysipelas, 32, mumps, 9 poliomyelitis, 4, dysentery, 13, cerebrospinal fever, 11, puerperal sepsis 18 enteric fevers 17, malaria, 1, other diseases (non infectious), 71, not yet diagnosed, 103

Deaths —In 126 great towns there were no deaths from measles, 1 (0) from enteric fevers, 1 (0) from scarlet fever, 12 (2) from whooping-cough, 31 (3) from diphtheria 41 (1) from diarrhœa and enteritis under 2 years, and 37 (1) from influenza The figures in parentheses are those for London itself

Bristol reported 1 death from an enteric fever Middlesbrough and Swansea each had 4 fatal cases of diphtheria

The number of stillbirths notified during the week was 167 (corresponding to a rate of 32 per thousand total births), including 16 in London

Births, Marriages and Deaths

BIRTHS

Belcher —On Dec 3, at St Andrews, the wife of Flying Officer J Rashleigh Belcher, M B —a daughter

Taylor —On Dec 6 at Crickhowell, Breconshire the wife of Dr A Brian Taylor, of Birmingham—a daughter

Warburton —On Dec 1, at Oxford, the wife of Dr E J Warburton, of Wallingford, Berks—a son

Wilson —On Dec 2 at Summercourt, Cornwall, the wife Dr C M Wilson—a daughter

MARRIAGES

Armin—Conway —On Nov 29, at Streatham, Richard Hayward Armin, M B, flying officer, R A F V R, to Margaret Mary Joynt Conway

Goldstein—Browning —On Dec 6, at Nottingham, Jacob Goldstein, M B, to Madge Browning

Tibbits—Wharton —On Nov 29, at Bournville, Stephen Tibbits, M R C S, of Warwick, to Joan Mary Wharton

Ward—Saunders —On Dec 2, in London, Philip Macready Ward, M B, to Margery Kathleen Saunders,

DEATHS

Cookson —On Dec 1 at the Staffordshire General Infirmary, Frederick Nesfield Cookson, M D Lond, F R C S aged 70

McCaughey —On Dec 7, at Liverpool, Francis George McCaughey, B A R U I, L R C P I

Mosse —On Dec 6, in Minneapolis, Francis Henry Mosse, M A Oxfd, M R C P, S P G medical missionary in China

Owens —On Dec 6, John Switzer Owens, M D Dubl, A M I C E, M I Mech E, F R S I

Sparkes —On Dec 5, at Scarborough, William Moore Bell Sparkes, D S O, M R C S, lieut -colonel, R A M C, retd

Turtle —On Dec 4, Godfrey de Bec Turtle, M D Durh, M R C P

Appointments

Pierre J H, M B Lond, F R C S M O (grade B) at Trinidad

Birmingham Accident Hospital and Rehabilitation Centre —The following appointments are announced —

Badger, F G, F R C S E deputy clinical director,
Howat T W L R C S E, first assistant, and
Wolfson, L J, M B Lond, D A, resident anæsthetist

A Birthday Present —Under the terms of Mr Bernhard Baron's will a grant is made every year on his birthday to hospitals and charities This year over £43,000 was distributed, of which £16,000 went to London hospitals and £10,000 to hospitals outside London

Medical Honour —The D S C has been awarded to Temp Surgeon Lieutenant Benjamin Crawshaw, L R C P E, for bravery and devotion to duty when H M S *Grimsby* was lost

PFEIFFER'S BACILLUS (INFLUENZAL) MENINGITIS

N MUTCH, M D CAMB F R C P
SENIOR PHYSICIAN TO GUY'S HOSPITAL SECTOR ADVISER IN MEDICINE E M S

THE discovery of the virus of epidemic influenza diverted medical attention from an earlier preoccupation with *Hæmophilus influenzæ* of Pfeiffer Disappointment had long been felt that the strain of this bacillus isolated from the respiratory passages rarely displayed much invasive power when inoculated into animals It is remarkable therefore that meningeal infections caused by Pfeiffer's bacillus should prove so uniformly fatal and completely resistant to all therapeutic measures which have been tried A number of examples of the condition have been noted in this *country during the past year and* the time is opportune for a review of our knowledge of the subject

Most of the observations on the disease have been made in America where it seems to be more common than in Britain Slawyk[19] described the earliest case in which the diagnosis was established bacteriologically Neal,[18] analysing 3139 cases, found that it was the fifth commonest American variety and accounted for 4 5% of all cases of meningitis Fothergill,[6] recording 51 cases at the Children's Hospital, Boston, over a 4-year period during which there had not been any outbreak of epidemic cerebrospinal meningitis, found that it was the commonest type of all and represented 23 1% of the meningitis group In this country it is comparatively uncommon but since August, 1941 3 undoubted cases and 2 other possible ones have been admitted to a Kentish Hospital of about 1000 beds We may owe our comparative immunity to a higher individual resistance to Pfeiffer's bacillus acquired in this land of the common cold—an idea which receives support from the bacteriological findings in the cerebrospinal fluid In American reports[2] the bacilli are described as occurring in strikingly great numbers In the cases reported here the bacilli have been so few that they might easily have escaped notice *Possibly the disease is sometimes overlooked* when laboratory facilities are inadequate The bacteriologist often fails to see or grow any organism from cerebrospinal fluid submitted to him from patients with suppurative meningitis There is a tendency to ascribe such failures to death of the bacteria during transport of the specimen or to the administration of sulphonamides before collection of the fluid, but it is conceivable that this unsatisfactory group may include a proportion of influenzal cases

CASE-HISTORIES

CASE 1—A soldier, aged 30, complained for 2 weeks of headache, giddiness and periodic weakness and sensation of swelling in his legs Ambulatory, and given sick leave Admitted on return with definite head retraction and occasional vomiting, normal cerebration Temperature 101 6° F, pulse rate 104, respirations 24 per min C S F pressure 250 mm, slightly opalescent, protein 0 09%, cells 46 per c mm (chiefly mononuclear), gram negative *bacilli* seen resembling *H influenzæ*, cultures sterile Blood serum agglutinated *H influenzæ* from case 5 at dilution 1 40 Two normal controls agglutinated same organism at 1 20 White-cell count 13,300 with 70% of polymorphs Treated with Sulphonamide E O S (80 g in 7 days) Temperature became normal in 24 hours Head retraction disappeared in 36 hours Recovery rapid, uninterrupted and complete

Note—Bacteriological *diagnosis* in this case not fully established Prognosis far better at 30 than during infancy

CASE 2—A youth of 16 Acutely ill for 48 hours with headache, fever and vomiting On admission semicomatose, with head retraction and positive Kernig's sign Temperature 102 6° F, pulse-rate 108, respirations 26 per min C S F pressure 280 mm, turbid, protein 0 28%, cells 7,840 per c mm (polymorphs 98%), extracellular gram negative bacilli seen resembling *H influenzæ but cultures sterile* Blood count white cells 14,900 with polymorphs 79% Treated with sulphonamide E O S (80 g in 7 days) Temperature normal in 48 hours Recovery rapid, *uninterrupted and complete*

Note—Bacteriological diagnosis not fully established Prognosis far better at 16 than during infancy

CASE 3—Infant, aged 17 months Acute onset with fever and irritability On admission, 36 hours later, quiet, considerable head retraction and positive Kernig's sign Temperature 102 2° F, pulse rate 116, respirations 44 per min C S F pressure 90 mm (rose later to 330 mm), opalescent (thick pus later), protein 0 16% (rose later to 0 45%), cells 84 per c mm (990 per c mm later and visible clots of pus), polymorphs 92%, gram negative bacilli seen in small numbers in six specimens and pure growth of *H influenza* obtained from each Treated by lumbar puncture and cisternal puncture and with sulphapyridine (34 5 g in 14 days, and after an interval of a week a second course of 32 g in 15 days) Partial defervescence during each course of sulphapyridine but general condition unaffected Stertorous and unconscious by 36th day, death Report on autopsy by Dr S J Hopkins Brain congested with flattening of the convolutions Thick yellow pus over base, extending forwards and surrounding optic nerves Lateral ventricles distended with thick yellow pus which extended throughout the ventricular system

CASE 4—Girl, aged 6 years Acute onset with headache and vomiting 24 hours before admission Semicomatose when first seen with moderate neck rigidity, Kernig's sign and opisthotonus Restless with well marked photophobia and meningitic cry Temperature 102 4° F, pulse rate 110, respirations 26 per min C S F pressure 200 mm, turbid, *protein* 0 24%, *cells* 4560 per c mm (polymorphs 97%), occasional extracellular gram negative bacilli seen, pure growth of *H influenzæ* on culture Treated with *sulphonamide* E O S (*12 5* g in 2 days) Day after admission *respiration became deep and rapid* Blood stained frothy *sputum*, *Cheyne Stokes respiration Death after 62 hours* of illness

CASE 5—Infant, aged 7 months Onset with coryza 12 days before admission Odd behaviour on 8th day of illness and *right sided twitching* on 10th day Not comatose until a few hours before death, but had tense fontanelle, muscular twitchings and head retraction Temperature 100° F, pulse rate 140, respirations 36 per min C S F pressure 210 mm, turbid, protein 0 1%, cells 1480 per c mm (polymorphs 92%), very occasional extracellular gram-negative bacilli seen on four occasions and pure growth of *H influenzæ* obtained from each of six specimens Treated with sulphapyridine (18 g in 8 days) lumbar puncture, cisternal puncture, intrathecal and intravenous serum from case 1 and from *normals* The fluid obtained by lumbar puncture on the 25th day of illness was almost pure pus but that obtained by cisternal puncture was only slightly opalescent A day later at autopsy thick pus was found on the surface of the brain Loculation, typical of this disease, was pronounced

Report on autopsy by Dr S J de Navasquez Dura mater adherent to arachnoid by very thick greenish purulent exudate so abundant over cortex that in many areas over vertex superficial pattern could not be seen On being stripped, dura retained some of exudate on its under surface Cerebral convolutions flattened and *sulci obliterated*, large subarachnoid collections of pus in island of Reil, basal cisterns and around medulla and throughout the spinal theca Ventricles filled with *similar exudate* Brain substance very soft but devoid of intracerebral suppuration Left lung showed some consolidation of lower lobe, remainder of lungs normal Myocardium pale and soft from fatty change Histology brain showed a severe purulent meningitis, which in places had penetrated beyond the arachnoid, which could not be seen, pia intact in the sections examined No intracerebral lesions Gram negative bacilli present in exudate, which on culture gave a pure growth of *H influenzæ* Lower lobe of left lung showed atelectasis and some hæmorrhage, but no inflammatory changes Liver and myocardium showed fatty change only.

BACTERIOLOGY

As seen in the cerebrospinal fluid, the *organisms are* gram-negative and usually extremely pleomorphic Although small bacilli are the predominant form, larger

Notes, Comments and Abstracts

BADGE OF OFFICE

Sweeping and garnishing never had their due while our world still clung to the Victorian belief that you came down to breakfast at eight o'clock and found the rooms clean and tidy, the fire burning and the coffee made, and that it was all done by magic Most of us have given up that any notion in private life, but *in hospitals the domestic* work still has to be done, and done early, and there is not much magic about it We have already noted (*Lancet*, Nov 22, p 655) that the Ministry of Health, with genuine appreciation of the contribution which hospital domestic workers are making towards winning this war, have decided to provide badges for them More insight has been shown in making the gesture than in choosing the design of the badge (shown in the illustration) The words "Ministry of Health" appear in silver letters on a red enamelled border, and "Hospital Service" is in blue on a silvered cross-bar The effect though honest is dispiriting Might not one of our penniless artists have been given the opportunity to do a national service and design a badge worthy of the ministerial inspiration?

Badges will be issued to all those workers on the domestic side in hospitals, including manual and supervisory staff, who are giving not less than 96 hours service a month, and it is estimated that 60,000 people will be eligible most of them women Many hospitals are short of domestic workers, and the Ministry of Labour has agreed that women giving full-time service in this capacity will not be asked to transfer to other war work, moreover women who are not in essential employment can, if they wish, ask to take up this work when they register No doubt the recognition of the value of the work which the badge implies will carry some weight with registrants

FELIX INFELIX

" limited quantities of damaged dried milk no longer suitable for human food can be issued to owners of warehouses and other food stores in which cats are kept to destroy vermin " (Hansard)

Milkless, my cat? Observe the regulations
  You cannot hope to share the infant's meed
In time of war the milk becomes the nation's,
  And who are you to swig the nation's need?
Yes, who indeed are you? Cry out upon us!
  A personage of note, not all unsung
The harmless necessary cat, your honours—
  The milkless mouser with a parching tongue
Harmless and necessary? What, no greater?
  Doyen of symmetry, address, aplomb!
The saucer, yawning like an empty crater,
  Shows where the Minister has dropped his bomb
Someone, I think, remarked you had your uses,
  Major Lloyd George unblushingly replied
"The modicum of milk reserved for pussies
  Is damaged, dated, damned, disdained and dried"

FLASHBACK

A Diary of World Affairs by Marcel Hoden (Penguin Books 6*d*) which covers the period from June, 1940, to April, 1941, is a useful reminder of the sequence of events during a tumultuous year which to most people was too confusing to be seen in perspective As a collection of facts as to who said and did what—and when—it is concise and readable Whether the author's optimistic interpretation of these events is as reliable only time will tell For a Frenchman disappointed in his own country's behaviour he seems a little too enthusiastic in his eulogy of ours Perhaps he ought to give up expecting too much of human nature, or disappointment may become his lasting portion

Burroughs Wellcome and Co inform us that, subject to priority demands, Tabloid sulphaguanidine 0 5 g is now available to the medical profession

Infectious Disease in England and Wales

WEEK ENDED NOV 29

Notifications—The following cases of infectious di were notified during the week smallpox, 0, scarlet fever, 1415, whooping-cough, 1959, diphtheria, 101, paratyphoid 16, typhoid, 7, measles (excluding rubella), 850, pneumonia (primary or influenzal), 1101, puerperal pyrexia, 124, cerebrospinal fever, 140 poliomyelitis, 15, polio-encephalitis, 1, encephalitis lethargica, 3, dysentery, 197, ophthalmia neonatorum, 83 No case of cholera, plague or typhus fever was notified during the week

The number of civilian and service sick in the Infectious Hospitals of the London County Council on Nov 26 was 1319, including scarlet fever, 168, diphtheria, 287, measles, 36, whooping-cough, 481, enteritis, 32, chicken pox, 36 erysipelas, 32 mumps 9, poliomyelitis, 4, dysentery, 13, cerebrospinal fever, 11, puerperal sepsis 18, enteric fevers, 17, malaria, 1, other diseases (non infectious), 71, not yet diagnosed, 103

Deaths—In 126 great towns there were no deaths from measles 1 (0) from enteric fevers, 1 (0) from scarlet fever, 12 (2) from whooping-cough, 31 (3) from diphtheria, 41 (1) from diarrhoea and enteritis under 2 years, and 37 (1) from influenza The figures in parentheses are those for London itself

Bristol reported 1 death from an enteric fever Middlesbrough and Swansea each had 4 fatal cases of diphtheria

The number of stillbirths notified during the week was 167 (corresponding to a rate of 32 per thousand total births), including 16 in London

Births, Marriages and Deaths

BIRTHS

Belcher—On Dec 3, at St Andrews, the wife of Flying Officer J Rashleigh Belcher, M B—a daughter

Taylor—On Dec 6, at Crickhowell, Breconshire, the wife of Dr A Brian Taylor, of Birmingham—a daughter

Warburton—On Dec 1, at Oxford, the wife of Dr E J Warburton, of Wallingford, Berks—a son

Wilson—On Dec 2 at Summercourt, Cornwall, the wife Dr C M Wilson—a daughter

MARRIAGES

Armin—Conway—On Nov 29, at Streatham, Richard Hayward Armin, M B, flying officer, R A F V R, to Margaret Mary Joynt Conway

Goldstein—Browning—On Dec 6, at Nottingham, Jacob Goldstein, M B, to Madge Browning

Tibbits—Wharton—On Nov 29, at Bournville, Stephen Tibbits, M R C S, of Warwick, to Joan Mary Wharton

Ward—Saunders—On Dec 2 in London, Philip Macready Ward, M B, to Margery Kathleen Saunders,

DEATHS

Cookson—On Dec 1, at the Staffordshire General Infirmary, Frederick Nesfield Cookson, M D Lond, F R C S, aged 70

McCaughey—On Dec 7 at Liverpool, Francis George McCaughey, B A R U I, L R C P I

Mosse—On Dec 6, in Minneapolis, Francis Henry Mosse, M A Oxfd, M R C P, S P G medical missionary in China

Owens—On Dec 6, John Switzer Owens, M D Dubl, A M I C E, M I Mech E F R S I

Sparkes—On Dec 5, at Scarborough, William Moore Bell Sparkes, D S O, M R C S, lieut colonel, R A M C, retd

Turtle—On Dec 4, Godfrey de Bec Turtle, M D Durh, M R C P

Appointments

Pierre, J H, M B Lond F R C S M O (grade B) at Trinidad

Birmingham Accident Hospital and Rehabilitation Centre—The following appointments are announced —
  Badger, F G, F R C S E deputy clinical director,
  Howat T W L R C S E, first assistant, and
  Wolfson, L J, M B Lond, D A, resident anæsthetist

A Birthday Present—Under the terms of Mr Bernhard Baron's will a grant is made every year on his birthday to hospitals and charities This year over £43,000 was distributed, of which £16,000 went to London hospitals and £10,000 to hospitals outside London

Medical Honour—The D S C has been awarded to Temp Surgeon Lieutenant Benjamin Crawshaw, L R C P E, for bravery and devotion to duty when H M S *Grimsby* was lost

The presence of toxic substances in the filtrates of *H fluenzæ* cultures was first noted by Parker[21] who epared a corresponding immune serum Utilising this oduct Wollstein[31] was able to protect the rhesus onkey from the effects of Pfeiffer cultures injected 24 ours earlier Kolmer[17] noted that cerebrospinal fluid om patients with influenzal meningitis is devoid of omplement a fact which has been verified by Fothergill nd Ward[10] Normal cerebrospinal fluid also is free om complement, but complement has frequently been etected in specimens from meningococcal and pneumoccal cases Pittman[23] therefore gave intrathecal jections of human complement as a therapeutic measure ut without success Fothergill and Ward[10] prepared orse antiserum with strong bactericidal powers and high gglutinin titre They showed that the bactericidal ffect of complement + antiserum is far greater than that of white blood corpuscles + antiserum and concluded hat the natural curative mechanism is one of complemental bacteriolysis They treated 5 cases with a mixture of complement (normal human serum) and bactericidal horse serum injected by lumbar puncture, cisternal puncture, through the anterior fontanelle and into the lateral ventricles through trephine openings, but every patient died Post-mortem examination revealed the usual loculation of pus in abscess-like cavities walled off from the general subarachnoid system Rittenberg[24] was able to record a successful case two years later and in 1937 Fothergill[6] published a substantial series of 201 cases with a modified mortality of 84 6% He had relinquished his heroic modes of injection and relied on simple lumbar puncture with occasional use of the cisternal route This method has now been employed by many workers[7, 27, 28] and the opinion is widely expressed[1] that Fothergill's serum and complement have no appreciable effect on the general course of the disease Moreover the issue is not affected materially when guineapig complement[27] is used instead of human serum The latest development of this type of therapy also comes from America Goodner and his colleagues[12, 13] showed that antipneumococcal serum from the rabbit is more effective than that from the horse and believed the difference to be due to the greater penetrating power of the smaller molecule of the rabbit immune bodies Alexander[2] therefore prepared an anti influenzal rabbit serum which is now in use clinically Good results are reported to have followed its use[6] but a final assessment of its utility still remains to be made

Sulphanilamide, sulphonamido-chrysoidin and sulphapyridine have each been used without definite success[1, 5, 27] Aleman[1] has given an analysis of 82 cases treated with sulphanilamide and 18 treated with sulphapyridine He also quotes substantial groups of patients treated with various combinations of these drugs and Fothergill's serum On the whole the fatality-rates are a little lower than those recorded before the introduction of these drugs But when the uncertainty of statistical deductions made from small numbers of cases is taken into account, and the inclusion of older children and adults in the series is noted, it is clear that proof of any benefit accruing from these drugs is still lacking It can be stated dogmatically that in this disease the sulphonamides have not shown that unequivocal power of control which they exert over the corresponding meningococcal infections

The problem of reducing the appalling mortality of influenzal meningitis has not yet been solved in spite of much endeavour I would suggest that less effort be made to inject remedial agents directly into the subarachnoid space The disease is essentially a septicæmia and a meningitis, not an encephalitis or a primary infection of the cerebrospinal fluid The fluid itself is a poor culture medium, but the organism survives vigorously for 24 hours or longer after the patient's death in contact with the tissues The meninges are well supplied with blood-vessels and curative bodies can most appropriately be introduced by that route

SUMMARY

Pfeiffer's bacillus meningitis is well known in this country though it is less common than in America

The responsible strains are capsulated gram-negative bacilli forming a single homogeneous serological group Strains isolated from the upper respiratory passages are relatively avirulent members of the Pfeiffer group and are serologically heterogenous

The disease is essentially one of infancy and does not often affect adults

Specific bactericidal substances are present in the blood of members of the immune age-groups but their titre in children between the ages of 6 months and 2 years is low

The clinical features are those of acute suppurative meningitis Loculated collections of pus often form Bacteræmia is common and persistent The diagnosis cannot be established without bacteriological examination Cultures (for example, on chocolate agar) must be made to differentiate the condition from those due to other gram-negative bacilli, such as *Strep meningitidis*

The prognosis is extremely grave and infants rarely recover Serological treatment has not yet met with any definite success and the sulphonamides have not perceptibly affected the fatality among infants The adult fatality rate is far lower than that of infants, recovery-rates must therefore be correlated closely with age-grouping if the curative effects of sera and chemotherapeutic substances are to be assessed Therapeutic assay could readily be made by studying the disease in infants of 2 years or under, and excluding adults and older children from the series

PFEIFFER'S BACILLUS MENINGITIS

RECOVERY WITH CHEMOTHERAPY

N M Jacoby, M D Lond, M R C P
REGISTRAR TO THE CHILDREN'S DEPARTMENT, GUY'S HOSPITAL
PHYSICIAN, E M S

A male infant, aged 1 year, was admitted to the County Hospital, Pembury, with a history of 24 hours' profuse vomiting, rigidity of the body, a fixed stare and drowsiness He had been well till the onset of this illness, and there was nothing relevant in the history He was extremely ill Temperature 104° F, pulse rate 150, respirations 60 He was pale, irritable and slightly dehydrated, there was some neck rigidity, but Kernig's sign was negative Except for a few purpuric spots on the loins there was nothing else abnormal Lumbar puncture showed turbid cerebrospinal fluid under slight pressure (not measured), protein 0 2%, 1600 polymorphs and 100 lymphocytes per c cm ; chlorides 725 mg per 100 c cm, no sugar Direct smears showed small numbers of gram negative bacilli of hæmophilus type Culture gave a pure growth of *Hæmophilus influenzæ*

Sulphapyridine (M & B 693) was given by mouth in the following doses 1st day, 3½ g, 2nd day, 3 g, 3rd day, 3 g, 4th day, 2½ g, 5th day, 2 g, 6th day, 2 g, 7th day, 1 g Total 17 g The temperature fell to normal at the end of 24 hours and did not rise again Although the child was much improved, he remained irritable for 3 days, and at the end of bacilli, coccoid, diplococcoid, and long filamentous forms are commonly seen. They cannot be cultured on ascitic or trypagar media but grow well on chocolate agar. Meningococci, pneumococci and hæmolytic streptococci also multiply freely on this medium, a circumstance which greatly simplifies the routine investigation of material. Several types of *H. influenzæ* have been differentiated, the two principal categories according to Pittman,[22] being (*a*) rough forms, a heterogeneous group of feeble pathogenicity (strains isolated from the respiratory passages are usually of this kind), (*b*) smooth forms developing capsules, a homogeneous group strongly pathogenic and characteristic of strains isolated from the cerebrospinal fluid. Fothergill and Chandler[8] by repeated subculture of meningeal strains were able in time to dissociate from them a number of avirulent variants which grew in rough colonies, were serologically heterogeneous, and closely resembled the innocuous type which frequents only the respiratory passages. Rivers and Kohn[26] demonstrated the homogeneity of the meningeal types by agglutination reactions. Pittman[22] confirmed the fact by precipitin tests. Wright and Ward[32] showed further that the rough forms were easily killed by bactericidal substances present in the blood, but that the meningeal smooth forms were far more resistant and therefore more fitted to invade the tissues. It can thus be taken as a firmly established fact that the meningeal strains of *H. influenzæ* isolated in America are with few exceptions smooth strains and mostly belong to one serological type—Pittman's group b. It is desirable that strains isolated in this country should be collected by one central laboratory and examined culturally and serologically.

AGE AND RESISTANCE

Infants and young children are particularly prone to meningeal infections. The age-incidence graph of every common variety shows a peak at some point between the ages of 6 months and 2 years. Influenzal meningitis conforms to this general rule. Of Neal's 3139 cases, 65% were in patients under 2 years. Rivers,[25] reviewing 193 cases, found that 79% of the patients were under that age. For Bloom's[4] 49 cases the figure was 62% and for Fothergill and Wright's[11] 76 cases it was 75%. It is almost unknown during the first 2 months of life and is commonest between the ages of 6 and 9 months. The incidence gradually falls off to reach a very low figure by 3½ years. Occasional cases are found among older children and adults. Fothergill and Wright found that the blood of normal adults possesses strong bactericidal powers against *H. influenzæ*. Blood from the umbilical cord at birth exhibited similar characteristics but during the latter half of the first year of infancy the bactericidal power of the blood is lost. They were able to demonstrate a close reciprocal relationship in each age-group between the incidence of influenzal meningitis and the bactericidal potency of the blood of the population in general. The freedom of the adult from this infection was thus closely correlated with the development of an acquired immunity, and the lower fatality-rate among older children and adults was explained.

CLINICAL FEATURES

The meningeal infection is of a frankly suppurative type and gives rise to symptoms closely simulating those of other forms of suppurative meningitis. A common cold or other infection of the upper respiratory passages often precedes the meningeal symptoms.[27, 11] The respiratory infection is not usually severe nor does it resemble infections with the influenzal virus; furthermore, meningitis due to Pfeiffer's bacillus is no more common during influenzal epidemics than at other times.[14] Dowds[5] has reported 2 cases in which the antecedent lesions were subcutaneous abscesses due to the Pfeiffer organism, but such cases must be very rare, and the usual portal of entry for the organism appears to be the mucosa of the respiratory tract. Fever, drowsiness, irritability, vomiting and neck rigidity develop rapidly as in cerebrospinal fever, but at times the onset may be as insidious as that of tubercular meningitis. Bacteræmia is a conspicuous feature[6] and blood-cultures may yield *H. influenzæ* persistently throughout the course of the disease. The prognosis is extremely grave and infants rarely recover. The patient may die during the first few days of illness (case 4) or death may be postponed for several weeks (case 3). In the latter event loculation of pus in the meninges usually occurs and it becomes impossible to relieve the symptoms of excessive intracranial pressure either by lumbar or cisternal puncture. Fluid withdrawn from below may then present characteristics widely divergent from those of fluid obtained from above. In spite of every effort to drain the subarachnoid space the pressure of the pent-up pus in various closed pockets may so compress the brain that all signs of the original convolutions are lost (case 5). Even in these circumstances, and with a thick stiff cream of almost inspissated pus lying over the surface of the brain, the patient may not lose consciousness entirely until the last. The outstanding feature of the disease is the inflammation of the meninges without any particular involvement of the brain.

Cerebrospinal fluid.—As withdrawn from the lumbar region, the cerebrospinal fluid may be opaque and turbid or merely opalescent. Leucocytes are abundant, the count varying from a few hundreds to several thousands per c.mm.; mononuclear cells are also found and may be as numerous as 200 per c.mm. Stained smears of the deposit show gram-negative bacilli and evidence of phagocytosis. Chlorides are low and protein and globulin are increased, the protein commonly ranging between 0.1% and 0.4%. The pressure may rise to values above 300 mm. of saline, but with the onset of loculation it tends to fall again to normal figures in spite of the high tension of pus imprisoned deeply in the skull.

DIAGNOSIS AND TREATMENT

Clinically the disease cannot be distinguished from other forms of suppurative meningitis. Diagnosis can only be established by bacteriological examination of the cerebrospinal fluid. In a certain proportion of cases the supernatant cerebrospinal fluid exhibits a precipitin reaction when mixed with the corresponding immune serum[6] but the usual diagnostic procedure is inspection of the gram-stained smear and incubation of the deposit inoculated on chocolate agar. Confirmatory culture is essential because other varieties of gram-negative bacilli sometimes cause meningitis—for example the salmonellas. The salmonella organism may occur in such pleomorphic forms in the cerebrospinal fluid as to mimic *H. influenzæ*[16] in stained smears of deposit. Bahrenburg and Ecker[3] collected 35 cases from the literature and many other cases have been reported in more recent years. Amongst the strains identified are *Salmonella schottmulleri* (*Bacterium paratyphosum B*), *S. enteritidis*, *S. paratyphi* (*Bact. paratyphosum A*), *S. panama*. The clinical features of salmonella meningitis resemble those of influenzal meningitis but a history of diarrhœa may replace that of respiratory catarrh. In each case the meningitis is of purulent type and polymorphonuclear leucocytes are numerous in the cerebrospinal fluid. The fatality-rate is very high in each disease, being 80 to 100% for influenzal meningitis and 91% in Bahrenburg and Ecker's collected salmonella cases. It will presently be shown that influenzal meningitis is resistant to sulphonamide therapy, but there are indications that salmonella infections can be controlled with these drugs.[16]

In so lethal a disease as influenzal meningitis the fatality affords a convenient inverse measure of the therapeutic success. At ages under 2 years the fatality is much greater than among older children and adults. Full consideration must be given to this fact in all attempts at comparative analysis. Among 78 cases admitted to the Boston Children's Hospital over a period of 12 years, Fothergill and Sweet[9] found only one case of spontaneous recovery. The following data are available:

—	Total cases	Fatality %		
		Mixed cases	Children under 2 yr.	Adults and children over 2 yr.
Rivers[25]	220	92	97	
Bloom[4]	320		96.7	
Neal, Jackson and Appelbaum[20]	111	100	100	
Wilkes Weiss and Huntington[30]	500		97.6	79.5
Fothergill and Sweet[9]	78		99	

The presence of toxic substances in the filtrates of *H luenzæ* cultures was first noted by Parker[21] who pared a corresponding immune serum · Utilising this oduct *Wollstein*[31] was able to protect the rhesus nkey from the effects of Pfeiffer cultures injected 24 urs earlier Kolmer[17] noted that cerebrospinal fluid m patients with influenzal meningitis is devoid of mplement a fact which has been verified by Fothergill[7] d Ward[10] *Normal cerebrospinal fluid also is free* om complement, but complement has frequently been tected in specimens from meningococcal and pneumo-ccal cases Pittman[23] therefore gave intrathecal jections of human complement as a therapeutic measure ut without success Fothergill and Ward[10] prepared orse antiserum with strong bactericidal powers and high glutinin titre They showed that the bactericidal fect of complement + antiserum is far greater than that f white blood corpuscles + antiserum and concluded hat the natural curative mechanism is one of complemental bacteriolysis They treated 5 cases with a ixture of complement (normal human serum) and acteriсidal horse serum injected by lumbar puncture, isternal puncture through the anterior fontanelle and nto the lateral ventricles through trephine openings, ut every patient died Post-mortem examination evealed the usual loculation of pus in abscess-like avities walled off from the general subarachnoid system Rittenberg[24] was able to record a successful case two ears later and in 1937 Fothergill[6] published a ubstantial series of 201 cases with a modified mortality f 84 6% He had relinquished his heroic modes of njection and relied on simple lumbar puncture with ccasional use of the cisternal route This method has ow been employed by many workers,[7 27 28] and the pinion is widely expressed[1] that Fothergill's serum and omplement have no appreciable effect on the general ourse of the disease Moreover the issue is not affected naterially when guineapig complement[27] is used instead f human serum The latest development of this type f therapy also comes from America Goodner and his olleagues[12 13] showed that antipneumococcal serum rom the rabbit is more effective than that from the orse and believed the difference to be due to the greater enetrating power of the smaller molecule of the rabbit mmune bodies Alexander[2] therefore prepared an nti influenzal rabbit serum which is now in use linically Good results are reported to have followed ts use but a final assessment of its utility still remains o be made

Sulphanilamide, sulphonamido-chrysoidin and sulphapyridine have each been used without definite uccess[1 5 27] Aleman[1] has given an analysis of 82 ases treated with sulphanilamide and 18 treated with ulphapyridine He also quotes substantial groups of atients treated with various combinations of these rugs and Fothergill's serum On the whole the atality-rates are a little lower than those recorded before he introduction of these drugs But when the uncertainty of statistical deductions made from small numbers f cases is taken into account, and the inclusion of older hildren and adults in the series is noted, it is clear that roof of any benefit accruing from these drugs is still acking It can be stated dogmatically that in this isease the sulphonamides have not shown that unequivocal power of control which they exert over the orresponding meningococcal infections

The problem of reducing the appalling mortality of nfluenzal meningitis has not yet been solved in spite of much endeavour I would suggest that less effort be made to inject remedial agents directly into the subarachnoid space The disease is essentially a septicæmia and a meningitis, not an encephalitis or a primary nfection of the cerebrospinal fluid The fluid itself is a poor culture medium, but the organism survives vigorously for 24 hours or longer after the patient's death in contact with the tissues The meninges are well supplied with blood-vessels and curative bodies can most appropriately be introduced by that route

SUMMARY

Pfeiffer's bacillus meningitis is well known in this country though it is less common than in America

The responsible strains are capsulated gram-negative bacilli forming a single homogeneous serological group Strains isolated from the upper respiratory passages are relatively avirulent members of the Pfeiffer group and are serologically heterogenous

The disease is essentially one of infancy and does not often affect adults

Specific bactericidal substances are present in the blood of members of the immune age-groups but their titre in children between the ages of 6 months and 2 years is low

The clinical features are those of acute suppurative meningitis Loculated collections of pus often form Bacteræmia is common and persistent The diagnosis cannot be established without bacteriological examination Cultures (for example, on chocolate agar) must be made to differentiate the condition from those due to other gram-negative bacilli, such as *Strep meningitidis*

The prognosis is extremely grave and infants rarely recover Serological treatment has not yet met with any definite success and the sulphonamides have not perceptibly affected the fatality among infants The adult fatality-rate is far lower than that of infants, recovery-rates must therefore be correlated closely with age-grouping if the curative effects of sera and chemotherapeutic substances are to be assessed Therapeutic assay could readily be made by studying the disease in infants of 2 years or under, and excluding adults and older children from the series

PFEIFFER'S BACILLUS MENINGITIS

RECOVERY WITH CHEMOTHERAPY

N M JACOBY, MD LOND MRCP
REGISTRAR TO THE CHILDREN'S DEPARTMENT, GUY'S HOSPITAL
PHYSICIAN E M S

A male infant, aged 1 year, was admitted to the County Hospital, Pembury, with a history of 24 hours' profuse vomiting, rigidity of the body, a fixed stare and drowsiness He had been well till the onset of this illness, and there was nothing relevant in the history He was extremely ill Temperature 104° F, pulse rate 150, respirations 60 He was pale, irritable and slightly dehydrated, there was some neck rigidity, but Kernig's sign was negative Except for a few purpuric spots on the loins there was nothing else abnormal Lumbar puncture showed turbid cerebrospinal fluid under slight pressure (not measured); protein 0 2%, 1600 polymorphs and 100 lymphocytes per c cm, chlorides 725 mg per 100 c cm; no sugar Direct smears showed small numbers of gram negative bacilli of hæmophilus type Culture gave a pure growth of *Hæmophilus influenzæ*

Sulphapyridine (M & B 693) was given by mouth in the following doses 1st day, 3½ g, 2nd day, 3 g, 3rd day, 3 g, 4th day, 2½ g, 5th day, 2 g, 6th day, 2 g, 7th day, 1 g Total 17 g The temperature fell to normal at the end of 24 hours and did not rise again Although the child was much improved, he remained irritable for 3 days, and at the end of

4 days all symptoms and signs had disappeared He was discharged fit on the 9th day after admission

Although this case recovered with the administration of sulphapyridine, no claim is made that the recovery was due to chemotherapy—it may or may not have been fortuitous But it is worth noting that the child had only one lumbar puncture This is a procedure I have followed in all cases of meningitis since chemotherapy has proved so effective In children, any therapeutic value the lumbar puncture may have had has now almost disappeared Its usefulness is solely diagnostic By watching the temperature and pulse charts, the clinical condition and the diminution of vomiting restlessness and signs of meningeal irritation, the progress of any case can be easily assessed Lumbar puncture need only be repeated in the rare cases where progress is unsatisfactory

I am grateful to Dr A W Taylor who did the pathological investigation

PHOTOELECTRIC METHOD OF ESTIMATING HÆMOGLOBIN

D K HILL,* B A CAMB A C PINCOCK
(*Department of Medicine, British Postgraduate Medical School*)

THE hæmoglobin content of blood can be accurately estimated by a photoelectric method In the method to be described the absorption of green light by the pigment is determined by means of a vacuum photocell in conjunction with a Lindemann Electrometer, obtained from the Cambridge Instrument Company The light source was a 12-volt 36-watt motor-car head lamp, supplied by six 2-volt 60-ampere-hour accumulators This gave a light free from the erratic variations seen when a light supplied from the mains was used The filament of the lamp was focused on the plate of the photocell by means of a lens (fig 1) The current through the photocell caused by the incident light is determined by measuring the potential drop across a fixed resistance of 200 megohms, connected in series with a potential of 120 volts The potential drop is measured by the Lindemann electrometer (fig 2)

The *photocell* is a General Electric Company's K M V 6 potassium-silver oxide type, which has a sensitivity to all parts of the visible spectrum, but not to the infra-red range The linear relationship between light and current, a special advantage of this type of cell, is maintained as long as the potential across the cell is above saturation value (fig 3) This cell is very stable and maintains its characteristics under varying conditions and over a long period of time

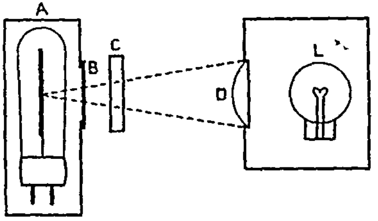

FIG 1—Light passes from the lamp (L) through the condensing lens (D) the fluid cell (C) and a colour filter (B) to the photocell (A) L and A are enclosed in light proof boxes

Lindemann electrometer —The needle of the electrometer is observed under a low-power objective, the eyepiece of the microscope having a graduated scale There is a linear relation between voltage and needle deflection provided the plate potential is kept at a certain value This plate potential is set by earthing one plate (by the switch S in fig 2) and adjusting the voltage on the other to give a reading of 28 scale divisions The other plate is then raised to the same potential, thus restoring the needle to its zero position (Each scale division on the ocular field = 0 1 mm , the microscope has a magnification of 60 ×)

The *colour filter* used was an Ilford No 807 , this gives a well-defined band in the green which is sufficiently narrow for Beer's law [1] to be approximately obeyed Beer's law states that the concentration of a pigment has a linear relationship to the optical density the light used is monochromatic

The *diluting fluid* used for the blood samples is saponin in 0 04% ammonia Previous workers Steinmann [2]) have advocated the use of stronger for the purpose of shifting the hæmoglobin d curve to the left in order to ensure complete of hæmoglobin to oxyhæmoglobin , but at the concentrations of ammonia (0 4%) conversion oxyhæmoglobin to methæmoglobin and then to is faster than was first imagined, as the following fi show

Ammonia concentrations	Oxyhæmoglobin percentage		
	8 min	60 min	120 min.
0 4%	98 6	96	94 2
0 04%	98 4	98	98

This observation has also been made by Szigeti [3]

To prepare a *calibration curve*, whole blood of a known oxygen capacity, previously determined by the method of Van Slyke, was diluted with varying proportions of diluting fluid The optical densities were measured in a cell with a fluid depth of 5 mm The curve relating optical density to O_2 capacity was nearly straight between 10 and 120% Newcomer (fig 4) The oxygen capacities of blood from different individuals may be the same, but their hæmoglobin concentrations determined by this method may vary by as much as 2% Blood from the same individual, however, gives constant concentrations by this method This discrepancy is probably due to the presence of pigments other than oxyhæmoglobin (e g , methæmoglobin) Minute traces of CO Hb often present in human blood create no significant error in hæmoglobin determination owing to the close correspondence of the extinction coefficients of oxy- and carboxy-hæmoglobin with the colour filter used

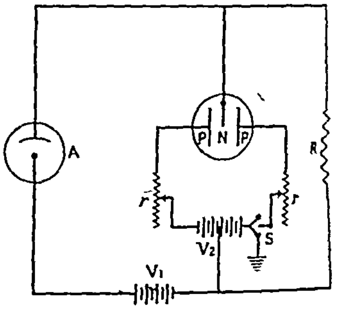

FIG 2—Voltage measuring circuit A, photocell , N, electrometer needle , P, plates , r plate potential resistances, S, switch for earthing one plate, R, 200 megohms resistance, V_1, 120 volt dry battery , V_2, 50 volt dry battery

TECHNIQUE

In estimating hæmoglobin 20 c cm of the blood to be examined is diluted with 3 c cm of diluting fluid Before the estimation is attempted the light must be switched on for at least 10 min , by which time the lamp has settled down to a constant illumination If the illumination is constant there is no drift on the electrometer needle The plate potential is adjusted as described above The needle deflection caused by incident light (i e , through filter B only) is then read (R_1) Then the needle deflection produced after transmission through the oxyhæmoglobin solution is read (R_2) A shutter is now placed in front of the cell, and the needle deflection when no light is transmitted is observed (R_3)

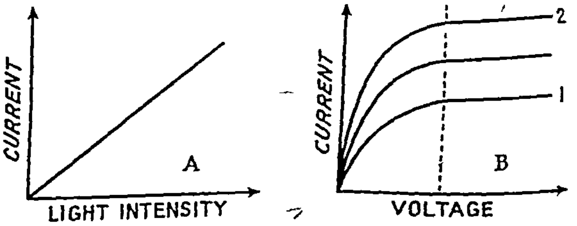

FIG 3—Relation between voltage current and light in a vacuum photocell A, With voltages above saturation value current is proportional to light intensity B Relation between voltage and current for constant light (1) low light intensity (2) high light intensity Note that unless a certain voltage ('saturation voltage ') is maintained, the current is not independent of voltage for a given light intensity

---

* Working on an M R C grant

[1] Beer s law for monochromatic light Optical density = log i_0/i = e c d = d ($e_1c_1 + e_2c_2$) Where i_0 = incident light, i = transmitted light, e = specific absorption coefficient, c = concentration, d = thickness of solution

[2] Steinmann, B *Arch exp Path Pharmal* 1938, 191, 237

[3] Szigeti, B *Biochem J* 1940, 34, 1460

As previously stated optical density of cell + pigment - diluting fluid (where zero on the scale equals no light)

$$= \log \frac{\text{Reading obtained with incident light}}{\text{Reading obtained with transmitted light}}$$

$$= \log \frac{R_1 - R_3}{R_2 - R_3}$$

he optical density of the cell plus diluting fluid alone is etermined in a similar manner This latter factor, which is constant, is subtracted from the total optical density, the difference being the optical density of the pigment alone The actual hæmoglobin percentage (Newcomer) may be read from the curve (fig 4), or, over a small range, by multiplying by a constant factor, since the curve is almost a straight line The reliability of the apparatus may be checked periodically by measuring the optical density of a standard neutral filter

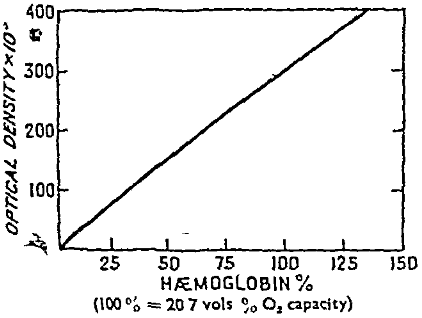

FIG 4—Relation between optical density and oxygen capacity of blood Hæmoglobin values (Newcomer) can be read off direct on horizontal scale

The accuracy of the method has been tested by repeated determinations on samples of oxalated blood The standard error is 0 4%

TREATMENT OF BEDCLOTHES WITH DUST-LAYING OILS

USE OF OIL-IN-WATER EMULSIONS

M VAN DEN ENDE,
M B CAPE TOWN
(*National Institute for Medical Research*)

JOHN C THOMAS,
M R C S , MAJOR, R A M C
OFFICER IN CHARGE OF A MILITARY LABORATORY

IT has previously been shown that very large numbers of dust-borne organisms are liberated from bedclothes during bedmaking, and we have described a method of reducing these which is effective both in the laboratory (van den Ende, Edward and Lush 1941) and in hospital wards (Thomas and van den Ende 1941, van den Ende and Spooner 1941) The method consisted of the application of pure, medicinal liquid paraffin to the bedclothing from a 30% solution of the oil in a light petroleum solvent (white spirit) Supplies of medicinal paraffin are, however, limited and its application from such an organic solvent introduces an unnecessary fire hazard Moreover, the process is expensive unless the solution is recovered during the laundering process and used repeatedly, and recovery requires special installations and modifications to the usual hospital laundry plants But the method, although perhaps unsuitable for adoption on a large scale, is highly effective in reducing the number of organisms distributed into the air during bedmaking Its possible importance in preventing the spread of infection and the relative simplicity of the principles involved have stimulated further research The results of experiments designed to find substitutes for liquid paraffin and to simplify the method of application form the subject of this paper

USE OF TECHNICAL WHITE OIL

The shortage of paraffinum liquidum B P has recently led, in the fourth addendum to the B P 1932, to the introduction of paraffinum liquidum leve B P which is similar to the paraff liq leve B P C 1934 This is a highly refined, inert mineral oil with a lower density and viscosity than the original oil, and represents the most refined type of what are known technically as "white oils" These white oils are available in considerable quantities, and we have used one differing from the new *B P product only in having a higher acid value*—that is, in being slightly less highly refined *

We have confined our work to the more highly refined white oils, since the less refined yellow spindle oils, although equally effective, cheaper and more readily available, all possess carcinogenic properties to a greater or lesser degree Carcinogenicity must obviously be excluded when an intimate contact between the oil and the patient's skin cannot be avoided Mr J M Twort of the Cancer Research Dept , University of Manchester, has tested the oils which we have used, and reports them to be non-carcinogenic

Twort showed that the alteration of refractive index of many oils after intraperitoneal injection into mice is related to its carcinogenicity (Twort and Lyth 1935, Twort, Lyth and Twort 1937, Twort and Twort 1938) Non carcinogenic oils remain unchanged or exhibit a very slight alteration (0 0003), while the refractive index of the highly active oils falls considerably (0 0040 to 0 0250 according to viscosity) The physical properties of the refined white oils referred to above and their specific refractive increments as tested by Mr Twort are recorded in table I Dr W E Gye is testing these oils for us by direct painting experiments on mice

For laboratory tests technical white oil was first applied from solution in white spirit in the same way as liquid paraffin in our earlier experiments In addition, technical white oil with which had been incorporated 20% of ammonium oleate as an emulsifying agent ("soluble technical white oil") was applied in organic solution to determine whether the presence of a wetting agent in any way interfered with the dust-laying properties of the oil The amount of oil absorbed by various textiles from solutions of different concentrations in white spirit was determined by ether extraction in a Soxhlet apparatus It was found that woollen and cotton materials retained approximately 3% and 9% by weight respectively of the oil when soaked in a 20% solution in white spirit This amount retained is slightly higher than the amount of medicinal liquid paraffin retained by the textiles after treatment with a 30% solution of liquid *paraffin in white spirit* The appearance and feel of the textiles treated with technical white oil in this concentration are not appreciably altered

To test the dust-laying effect, strips of the various textiles were infected either with a serum-broth culture of a Lancefield's group C hæmolytic streptococcus and allowed to dry in the incubator overnight, or with a powder of dried streptococci mixed with autoclaved floor dust They were then mechanically *beaten in a specially* constructed machine, which was used also in earlier experiments with medicinal liquid paraffin (van den Ende, Edward and Lush 1941) The numbers of bacteria liberated from treated textiles were compared with those from similarly infected control strips counts being made up to 12 min after beating The amount of visible dust liberated by the beating was roughly measured with a photoelectric attachment The results of these experiments, which are summarised in table II, showed that both ordinary and soluble technical white oil were efficient dust-layers Applied in a 20% solution, the mean reduction was 96 6% for dry and 100% for wet organisms This reduction is as good as that previously obtained with a 30% solution of liquid paraffin in white spirit

OILS APPLIED FROM STABLE WATERY EMULSIONS

The textile industry employs a wide variety of oil-in-water emulsions during spinning to ensure pliability of the yarn, this oil is later removed by washing the woven fabric in water The use of similar emulsions for the application of dust-laying oils to bedclothes would greatly simplify the oiling process and reduce the expense of the process Organic solvents are unnecessary and the oil can be added to the rinsing tank, thus obviating the necessity for additional laundry equipment Furthermore the ease of washing bedclothes treated with "water-soluble" oil instead of ordinary liquid paraffin greatly simplifies the laundering of bedclothes after use

Preliminary experiments with "soluble" oils showed that the nature of the emulsion was of prime importance

---

* This oil, refined by the Manchester Oil Refinery Ltd , was supplied to us by Stemco Ltd. and is referred to as "Technical White Oil" Other white oils which are available include "Marcol" and "*Wyrol B*" (both of American manufacture) and "Puremore" (English manufacture)

TABLE I—PHYSICAL PROPERTIES OF SOME "WHITE MINERAL OILS"

Technical white oil "Puremore" (English)	0 850				25 7	1 4704	Nil	Inert

* Mr J M Twort has kindly supplied these figures

Oils emulsified with oleates and stearates alone were unsuitable, since the final emulsion was not stable in the centrifuge These dense white emulsions broke down in the hydro-extractor, the result being an uneven oiling of the clothing We came, therefore, to regard any opaque creamy white emulsion as unsuitable The majority of commercial oils and those prepared with many of the commercial emulsifiers fell into this class and were discarded without further investigation A number indeed had to be discarded earlier on account of the low degree of refinement of the mineral oil used in their manufacture Some were crude kerosenes, others spindle oils with the addition of suitable emulsifiers These crude oils were not applied to bedclothes on account of their potential carcinogenic activity A number of commercially available oils prepared from high-grade white oils were supplied to us in translucent, centrifuge-stable emulsions in water (Two of them (Olinol nos 1 and 2) have been used in hospital trials as well as in laboratory tests These contain 35% and 65% respectively of white oil emulsified with sulphonated naphthenic hydrocarbons which in themselves may have some bactericidal action Mr J M Twort tested a sample of olinol no 1 for us, and found that there was a very slight fall in refractive index (0 0016) after recovery from injected mice

TW = technical white oil STW = technical white oil with 20 % emulsifier (ammonium oleate) A = during the first 2 min after beating B = during the 5 min period 7–12 min after beating * = too greasy to the touch † = average of two experiments tr = trace ‡ = only results of experiments in which dry streptococci were used are given The results of experiments with sprayed organisms were better but since this effect can be attributed partly to the bactericidal action of the emulsifier against wet organisms the results cannot be included in tests for dust laying power

The general principles underlying the preparation of stable oil-in-water emulsions have been extensively investigated (Schulman and Cockbain 1940, Alexander and Schulman 1940, Rideal and Schulman 1939) Briefly, to obtain a stable emulsion, the emulsifying complex must contain an oil-soluble and water soluble fraction Under these conditions, molecules of both types are held at the oil water interface, and the emulsion remains stable Much of their work on mineral oil ("Nujol") emulsions was done with long chain alcohols and higher alkyl sulphates as the oil-soluble and water soluble agents respectively On this basis we have been able to prepare emulsions of "white oils" in water in which the oil dispersion is so fine that the final emulsion is almost transparent For these experiments we tested a number of emulsifying and wetting agents—cetyl alcohol, cetyl pyridinium bromide, sodium lauryl sulphonate, triethanolamine oleate, oleic acid, ammonium oleate, sodium and aluminium stearate, and a large number of commercial agents We finally found that the most suitable solutions or permanent fine emulsions could be prepared from technical white oil, cetyl

alcohol, Turkey red oil (sulphonated castor oil), ester salts (a homologous group of secondary higher alkyl sulphates with a carbon chain length of 10 to 18), and cresylic acid in various proportions. Details of two oils (nos. 8 and 12) prepared with these ingredients are:

Oil No. 8

	Parts by weight
Sulphonated castor oil (50% neutral finish)	210
Technical white oil	105
Ester salts solution (25% active material in water)	105
Cetyl alcohol	30
Cresylic acid	50

Oil No. 12

	Parts by weight
Sulphonated castor oil (50% neutral finish)	225
Technical white oil	175
Ester salts powder (60% active material)	70
Cetyl alcohol	70
Cresylic acid	70

Dissolve cetyl alcohol in technical white oil with aid of heat, stir in sulphonated castor oil, followed by ester salts and cresylic acid. Sodium sulphate deposits in oil no. 12 on standing and the clear oil is decanted next day. These oils are a clear dark brown colour and give instantaneous, transparent emulsions in water. Sulphonated castor oil, although soluble in water in all proportions, is not suitable for application alone to fabrics, as it renders them rather hard and sticky and is by itself not an efficient dust layer.

LABORATORY TESTS WITH OIL-IN-WATER EMULSIONS

Dust-laying effect.—Laboratory tests were made with the following soluble oils: oil no. 8, oil no. 12, olinol no. 1, olinol no. 2, Amoa A3 mixed with an equal volume of technical white oil, sulphonated castor oil (50% neutral finish) and sulphonated castor oil containing 10% cresylic acid. The results were compared with those obtained with technical white oil applied from solution in white spirit. Textiles treated with various concentrations of these oils were also assayed for their content of ether-soluble oil by extraction in a Soxhlet apparatus. Blankets treated with a 20% solution of oil no. 8, amoa and technical white oil, olinol and olinol no. 2 absorbed approximately the same amount of ether soluble oil as blankets treated with a 20% solution of technical white oil in white spirit. The dust-laying effect of these oils was tested in the same way as previously described for technical white oil.

TABLE IV—BACTERICIDAL ACTION OF OILS IN BROTH AGAINST VARIOUS ORGANISMS. CONTACT FOR 24 HOURS AT 37° C

The figures refer to the highest dilution of the oil in broth which is bactericidal

Oil or emulsifier	B. hæmolytic streptococcus Group C	*Staphylococcus aureus*	*Bact. coli*	*Proteus*	*Ps. pyocyanea*

Ester salts	320	320		Not tested	
Crude naphthenic sulphonates	1280	1280		„ „	

The results of these tests (table III) show that the dust-laying effect of oil applied from fine emulsions in water is as striking as that of oil applied from organic solutions. The oil treatment had apparently a much greater effect in preventing dust-borne infection from the fabrics infected with sprayed organisms than from those in which the fabric was treated with dry organisms. This was subsequently shown to be due to the bactericidal action of the various emulsifiers, and presents an added advantage where the natural infection of blankets, &c. depends on the deposition of relatively large, moist droplets from the upper respiratory tract. This bactericidal action is borne out by direct tests, and is also apparent in hospital trials with blankets oiled by this method.

The *bactericidal action* of the oils, and of the crude emulsifying agents, was tested against *Streptococcus pyogenes* (group C), *Staphylococcus aureus*, *Proteus*, *Bacterium coli* and *Pseudomonas pyocyanea*, both in vitro and after application to blankets. For tests in vitro serial dilutions of the oil in broth were inoculated with a standard dose (about 2 million) of an overnight culture of the test organism, and stroke cultures were made on appropriate solid media after varying incubation times up to 24 hr. Subcultures were also made into broth of sufficient volume to avoid the bacteriostatic effect of the oils. All the oils tested were bactericidal in high dilutions, oils nos. 8 and 12 proving the most potent. This is probably due to the fact that they contain cresylic acid as well as the emulsifying agent. *Strep. pyogenes* and *Bact. coli* were most easily killed, *Staph. aureus* and *Proteus* being more and *Ps. pyocyanea* most resistant (table IV). Dilutions of 1/64, however, killed all the organisms in every case.

This antiseptic action in broth is paralleled by the activity on blankets against wet organisms (table V). To show this, strips of blanket were oiled in the usual manner, and small squares were equally inoculated either with a coarse spray of a serum broth culture of *Strep. pyogenes* (group C) or with a mixture of dried organisms and sterile, finely sieved dust. The strips were left overnight, then small squares (1/9 sq. in.) were cut from the centre of each and transferred to screw-capped bottles containing 100 ml. broth and a number of glass beads. These were shaken vigorously for 10–15 min., and appropriate amounts were plated out into blood-agar. Colonies were counted after 48 hr. aerobic incubation. Control tests were made with untreated blanket and with blanket treated with technical white oil in white spirit (which has no bactericidal activity). In all cases with the wet organisms, the final counts showed a minimum kill of 99·5%. With dry organisms there was less striking reduction. The greatest was with oil no. 8, which gave total counts of approximately 300,000 per blanket

TABLE V—BACTERICIDAL EFFECT OF DUST-LAYING OILS AND EMULSIFYING AGENTS ON A WOOLLEN BLANKET AGAINST WET AND DRY STREPTOCOCCI

Treatment of blanket	Plate counts A	Plate counts B	Total organisms in test fabric	Per cent. reduction
IMPREGNATION WITH COARSE SPRAY OF SERUM BROTH CULTURE

Turkey red oil and 10% cresylic acid 1 2	1016 96	880 104	3·79 × 10⁶ 4·00 × 10⁶	78·8

A and B are duplicate samples. 1 = no. of organisms from 0·5 c.cm. of a 1/20 dilution of the broth washings of the test fabric. 2 = no. in 0·5 c.cm. of a 1/200 dilution.

square compared with control counts of 18 million These tests with dry organisms were, however, subject to a number of possible errors which make their interpretation difficult The size of the test squares and the infecting dose were judged as carefully as possible, but when infection of the fabric (far greater than is likely to occur naturally) is produced with a dry powder of streptococci, even small errors in measurement of infective dose would produce a large final difference Moreover, there is the possibility that in spite of vigorous shaking the organisms in the depths of the fabric are not liberated sufficiently quickly, so that on contact with the broth the oil would exert its bactericidal action as against wet organisms The reduction in bacterial count after application of dry organisms has, however, been shown repeatedly, and it seems reasonable to conclude that some bactericidal action was shown against dried organisms although it was not as great as against organisms applied in the presence of moisture

HOSPITAL WARD EXPERIMENTS

Two clean sets of blankets, sheets, pillow-cases, counterpanes and pyjamas, each sufficient for a single bed cubicle, were treated with olinol no 1 and no 2 respectively Each set of bedclothes was thoroughly soaked in a 20% water solution of the oil, spun in a hydro-extractor and finally dried in the hot-air drying chamber

Our experimental work in hospitals has so far been done with initially clean bedding, and we have used a separate soaking tank for applying the oil (as a 20% solution) This is unnecessary when one has to deal with dirty "linen" which is being washed in the ordinary laundry rotary washing machine These machines perform the complete washing and rinsing process without removal of the linen, and it is usual to finish with one warm and two cold water rinses The amount of water used is measured in inches by an indicator on the back of the machine, it is not difficult to calculate the amount of water introduced for the final cold rinse in gallons, and also the amount of oil which has to be added to this to give a 20% solution This amount of oil can then be added through a vent, with which all the machines are fitted, at the beginning of the last rinse for each charge of linen There is thus no need to open the machine at all A run of 8–10 min is sufficient to ensure impregnation of all the clothing, which can then be transferred to the hydro-extractors and spun The effluent from these can be collected in a tub by substituting a right angled outflow instead of the usual vertical one which normally runs direct to waste (the outflow is only fixed by two bolts through a gasket, so that such an alteration is simple and inexpensive) When sufficient has been collected in the tub, the first cold rinse in the washing machine can be let out, and instead of filling up with cold water and fresh oil, the machine opened and the contents of the tub tipped in for the second rinse This process can be repeated several times and results in very little waste

Two extra blankets were included with those for the trial with olinol no 1 One of these was cut in two, half being left untreated as control and the other half treated These halves were used in laboratory tests for assay of oil content and dust-laying properties The treated half was found to contain 3 35% and the control 1 6% of ether-extractable oil

The presence of 1 6% of ether soluble oil in untreated blankets is unusual unless the blankets are new Usually after repeated washing hospital blankets contain less than 1% of "oil" A sample of the natural oil which has been extracted with ether in a Soxhlet apparatus has been tested for us by Dr C Rimington He concluded that it was probably lanolin Reapplied to a repeatedly washed blanket strip it resulted in moderately effective dust laying Similarly a dust-laying effect is observed after the application of commercial lanolin The application of lanolin, however requires the use of organic solvents, and the texture of textiles treated with it is somewhat unpleasant in comparison with that after mineral oil treatment

The dust-laying effect of the treatment was also shown in laboratory tests on strips of these blanket samples (table VI) The second blanket was also divided in two and both halves were treated Half was placed at the periphery of the hydro-extractor and the other half at the centre, both being subsequently assayed for oil content The object of this was to determine whether this method of soaking and centrifugation resulted in a uniform impregnation of the blankets That this is so is shown by the fact that the peripheral and central halves contained 3 3% and 3 4% respectively of ether-soluble oil

TABLE VI—DUST LAYING EFFECT OF VARIOUS OILS AND EMULSIFYING AGENTS ON STRIPS OF HOSPITAL BLANKET

Test organism dry streptococci

Treatment	Bacterial counts		Visible dust liberated	Per cent reduction in bacterial counts	
	A	B		A	B

20% Turkey red oil in water	224	60	+	34 1	66
20% technical white oil in white spirit	9	1	–	97 4	99 4
20% oil no 12 in water	28	0	–	91 7	100
20% oil no 8 in water	35	3	–	89 7	98 3
20% (Amoa A 3 + technical white oil equal parts) in water	4	0	–	98 8	100
20% (Turkey red oil + 10% cresylic acid) in water	290	42	+	14 7	76 7

A, during the first 2 min after beating, B, during the 5 min. *period 7–12 min after beating*

Oil assays were also made on the liquor from the soaking tank as well as from the hydro-extractor outflow at the beginning, during, and at the end of its run The amounts of ether-soluble material recovered from these samples did not differ significantly It was concluded, therefore, that the liquor recovered from the hydro-extractor can justifiably be returned to the soaking tanks for further use

On the day on which the bedding was treated, two patients were admitted to single-bed cubicles (similar to those used in our previous experiments) One was suffering from acute streptococcal tonsillitis (type 12/27) and the other from facial erysipelas (*streptococcus type 3*) The cubicles were carefully cleaned the floors treated with spindle oil, and the men placed in clean bedclothes from the linen store The patients were left for 48 hr, when air-counts were made on 5 c ft volumes of air before, during and after vigorous bedmaking All samples were taken on to gentian-violet blood agar plates with a slit sampler (Bourdillon, Lidwell and Thomas 1941) The colonies were counted after 24 hr aerobic incubation of the plates All the bedding was then removed, the oiled bedclothes substituted and similar counts made daily for 8 days In each cubicle the control counts were approximately 2000 per c ft and large numbers of type-specific streptococci were recovered from the air during and after bedmaking The mean reduction of organisms liberated from the oiled blankets during vigorous bedmaking was 99 4% and 98 5% in the two cubicles respectively It is significant that at no time during the period when treated bedclothes were used was a single streptococcus recovered from the air in spite of the fact that the organism could constantly be isolated from both patients In our previous experiments with liquid paraffin, although treatment of bedclothes with the oil resulted in reduction in numbers we usually recovered small numbers of streptococci from the air during the test period, and these numbers tended to increase with time It seems reasonable to conclude therefore that the oil had exerted a bactericidal action on the streptococci deposited on the blankets This finding could best be accounted for if the streptococci were deposited in a moist state, as would be the case if they were deposited in large droplets from the respiratory tract

The reduction of the numbers of air-borne bacteria was not wholly due to this bactericidal action, but was at least in part due to the reduction in the amount of dust liberated from the bedclothes This could be shown by collecting with a slit sampler the dust liberated by shaking the blankets, on stationary glass slides instead of rotating plates of nutrient medium

DISCUSSION

Our experiments have shown that mineral oils other an liquid paraffin may be used to lay the dust on dclothes A number of these oils are available The uder ones, such as the spindle oils, are carcinogenic d unsuitable for application to bedclothes where timate contact between the patient's skin and the oil e unavoidable The dermatitic factor has also to be nsidered, and while more highly purified and inert oils e available these should be used Such oils are the ghly refined white oils, and all the oils of this type hich we have tested have proved to be efficient dust-yers

The fact that these oils, with the aid of suitable wetting nd emulsifying agents, can be made to give centrifuge-able emulsions with water overcomes the original ifficulty of application from an organic solvent, and akes large-scale treatment of bedclothes a practical ossibility in hospital laundries We have shown that hese oil-in-water emulsions are almost as efficient dust-ayers as the oils applied from white spirit, and that the mulsifiers used are themselves bactericidal under atural conditions This action is most pronounced gainst wet organisms and is relatively slight against dry bacteria

The killing of dried organisms is probably not of such practical importance as the killing of those in the large, moist droplets exhaled from the upper respiratory tract Hare (1940) demonstrated a downward stream of such droplets from the mouth and nose of infected persons, and from the numbers of streptococci which we have previously shown to accumulate in blankets in relatively short times, each of these droplets must contain very large numbers of organisms Bourdillon and Lidwell (1941), by means of flash photography, have shown that the number of large droplets expelled during a sneeze is enormous, and since a person normally lowers his head when sneezing the number of organisms projected on to the bedclothes when a person in bed sneezes is very great Under normal circumstances these droplets would then dry and remain as potentially infective particles to be liberated when the bedding is shaken It is important that bedclothes treated with the soluble oils not only retain most of the organisms within the actual fabric but also kill the organisms in these droplets before they can dry Furthermore, the application of oils from stable watery emulsions renders the process much less expensive, frees it from the danger of fire, and makes it practicable even for modestly equipped hospital laundries

SUMMARY

Technical white oils are effective dust-layers for bedclothes and are not carcinogenic

These oils can, by the use of suitable emulsifying and wetting agents, be made to give centrifuge-stable emulsions in water Such oil-in-water emulsions provide an easy method of applying the oil to bedclothes, and a large-scale method is outlined

The emulsifying agents used in making these "soluble" oils impart to the bedclothes potent bactericidal activity which has been shown to be effective against moist droplets both in the laboratory and in hospital trials Their bactericidal action against dry organisms was slighter

The use of soluble oils in hospital trials resulted in a 99% reduction in the number of organisms liberated during bedmaking No hæmolytic streptococci were liberated from the treated bedclothes of two patients with hæmolytic streptococcus infections This can be explained at least in part by the bactericidal action of the oil against moist organisms, especially if the infection of the bedclothes is regarded as being derived from large droplets from the respiratory tract

We are indebted to Mr J W C Phillips for his advice and interest, Mr J M Twort and Dr W E Gye for testing the carcinogenic properties of our oils; Dr S D Elliott for typing our streptococcal strains, Dr J H Schulman and Mr J E Lovelock for help in preparing the soluble oils, Dr C Rimington, Dr C H Andrewes and Dr R B Bourdillon for much other help and advice, Brigadier L T Poole, director of pathology, A M S, and Colonel E B Marsh for allowing one of us to take part in this work, and to the managing directors and technical staff of Amoa Chemical Co Ltd, A Boake Roberts & Co Ltd, Olinol Ltd, Stemco Ltd and Technical Products Ltd for supplying many of the oils and emulsifiers

HYPERCHROMIC ANÆMIA IN AN INFANT

RESPONSE TO LIVER EXTRACT

LESLIE COLE, M.D CAMB, F R C P
PHYSICIAN TO ADDENBROOKE'S HOSPITAL, CAMBRIDGE

LIVER extract is not often used in the treatment of anæmia in infancy and reports of success are few This case is being reported because, when the chance of recovery seemed slight, a single dose of Anahæmin was followed by steady improvement and evidence of blood regeneration It is regrettable that the records are incomplete, for the first blood-count was done 48 hours after the liver extract had been given

Bachman[1] described a case of macrocytic hyperchromic anæmia in an infant aged nine months and reviewed 17 others from the literature, of which 7 including his own were treated and appeared to respond to liver extract All 7 improved or recovered, 3 were not followed up but there was no immediate recurrence when it was discontinued in 3 of the other 4 Langmead described a case of pernicious anæmia in an infant aged thirteen months with severe hyperchromic anæmia, megalocytosis, icterus index 17 6 units achlorhydria in response to histamine and a reticulocyte response of 19% to Campolon Smallwood[3] refers to a case of subacute hæmolytic anæmia which recovered only when liver treatment was begun but did not relapse when it was discontinued, he considered that this was due to temporary exhaustion of anti-anæmic principle after a long period of hæmolysis and erythrogenesis In no case described does the anæmia appear to have been more than a temporary effect, once the anæmic crisis has been tided over by liver or blood-transfusion maintenance treatment with liver has not been shown to be necessary This is in contrast to the pernicious anæmia of adults, where deficiency is nearly always permanent and treatment has to be continued to prevent relapse

CASE-HISTORY

A girl, aged 3 weeks No history of anæmia in the family No apparent deficiency in the mother's diet This was her first child Pregnancy normal, breech presentation with easy delivery, birth weight 7¼ lb The child did not suck well and was breast fed for only a week She was then given half-cream Cow and Gate, seven feeds daily She failed to make progress so this was changed to albumin water, 3 oz, alternating with diluted cow's milk, 3 oz (2 parts milk to 3 parts water) The stools were inclined to be loose and on one occasion contained blood, and there was occasional vomiting On admission on May 16, 1941, the child was very ill and rather dehydrated Temperature 104° F, pulse rate 160, respirations 40–60 Signs of general bronchitis and a suggestion of bronchopneumonia Spleen not palpable and liver not enlarged Stools loose, numerous and occasionally dark Bowels often open after feeding Never any trace of jaundice Urine normal Diagnosis bronchitis and possibly bronchopneumonia Weight on May 26, 6 lb 10 oz Diet from May 16 until June 6 she was given Frailac two or three hourly, from June 7 she was graded on to half-cream Cow and Gate three hourly, on June 18 additional Dextri-maltose was added to each feed, and this was continued until

her discharge During the first 24 hours 0 75 g of sulphapyridine was given by the mouth Since there was no response 3 c cm of azosulphamide (Prontosil Soluble) was given intramuscularly on May 17 and 0 75 g of sulphanilamide daily until May 22 The daily dose was then halved until May 25 when it was stopped There was considerable improvement and the temperature became normal on May 18 and remained so until the 27th There was no gain in weight, however, and the stools on the 20th gave a strong reaction for occult blood On the 27th the temperature rose again to 103° F and an empyema was suspected, but radiography of the chest showed no evidence of lung disease The stools then became more frequent and on May 30 a small amount of visible blood was passed Vitamin K, 0 5 c cm, was then given intramuscularly During the next three days the temperature remained up and the general condition rapidly deteriorated On June 2 obvious anæmia was apparent for the first time The baby was then desperately ill with a temperature of 103° F and an almost uncountable pulse It was clearly no use giving iron by the mouth, and blood-transfusion was out of the question, so 1 c cm of anahæmin was given intramuscularly Twenty-four hours after this injection there was an astonishing change, the whole clinical condition improved, dehydration and diarrhœa became steadily less, and the child began to take her feeds better and to gain weight for the first time This progress continued without interruption until discharge Within a week the stools had become almost normal in number Her weight chart and blood counts are shown in fig 1 By the beginning of July she weighed 7½ lb, seemed healthy in every way and has remained well since without further treatment

BLOOD COUNTS AFTER ANAHÆMIN, 1 C CM, HAD BEEN GIVEN ON JUNE 2

—	June 4	June 21	July 3	July 17
Red cells	2,065,000	3,840 000	5,140 000	6,300 000
Hæmoglobin	54%	62%	84%	98%
Colour index	1 24	0 82	0 82	0 83
White cells	15,600	17 000	24,000	
Polymorphs	6085 (39%)	5400 (32%)	6480 (27%)	
Eosinophils	465 (3%)	340 (2%)	960 (4%)	
Lymphocytes	8425 (54%)	9860 (58%)	14 400 (60%)	
Mononuclears	0	850 (5%)	2160 (9%)	
Myelocytes	465 (3%)	510 (3%)	A few immature polymorphs	
Myeloblasts	160 (1%)			
Normoblasts	1 per 200 white cells	20		
Megaloblasts	6 per 200 white cells			
Primary erythroblasts	5 per 200 white cells			

The blood count findings are shown in the table Price-Jones curves are in fig 2 On June 12 blood films showed considerable megalocytosis and variation in size of red cells, megalocytes 12%, microcytes 1%, mean diameter 7 6 μ On July 10 there were very few megalocytes (1%) and less variation in size of red cells, megalocytes 1%, microcytes 1%, mean diameter 7 3 μ Reticulocytes June 9, 22 5%, June 12, 17 8%, June 14, 17 5%, June 21, 5 6%, July 3, 4 4%, July 10, 1 9% Fragility on July 11 hæmolysis begins at 0 38% saline and is complete at 0 26%

Fractional test-meal on June 25 30 c cm 3½% alcohol, no histamine given, 0 036 free hydrochloric acid present in sixth sample Wassermann reaction, negative

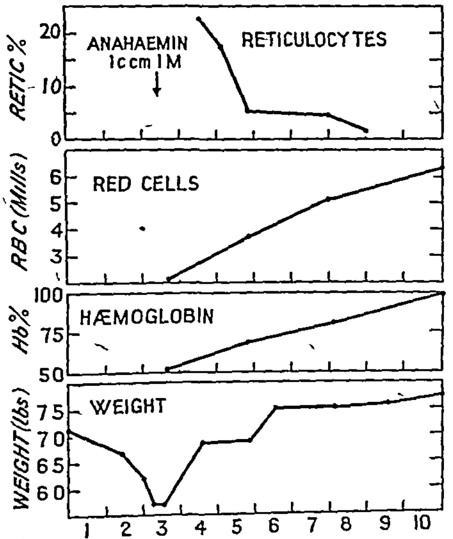

FIG 1

DISCUSSION

In this case the sudden onset of anæmia may have been due to hæmorrhage but was probably partly hæmolytic From its response to treatment it appears to have been due essentially to a temporary lack of anti-anæmic principle or one of its precursors, for the diet was qualitatively unchanged for a fortnight before anahæmin was given until recovery was well advanced The only additional treatment was a single injection of vitamin K four days before the anahæmin, and during this four day progress was rapidly downhill The cause of the deficiency is difficult to explain For the first three weeks of life the diet was certainly deficient in total calories, proteins, vitamins and iron, and as there was also a severe general infection with considerable intestinal disturbance absorption was also probably impaired There was also some loss of blood from the intestinal tract Such a combination in a child of this age is by no means rare but it causes hypochromic anæmia, and not hyperchromic anæmia as in this case Two other possibilities remain—first, that the child started life with deficient stores of anti-anæmic principle, secondly, that treatment with sulphapyridine and sulphanilamide were contributory factors It might also be argued that the recovery was not due to liver extract but was spontaneous, but the striking reticulocyte response is against this The Price-Jones curves although they show some degree of megalocytosis, becoming less after treatment, are within normal limits for the age of the patient

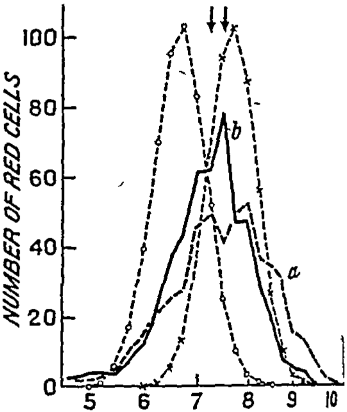

FIG 2

SUMMARY

A case of hyperchromic anæmia in an infant is described in which complete clinical and hæmatological recovery followed a single injection of anahæmin

No qualitative alteration in the diet was made for a fortnight before anahæmin was given or until recovery was well advanced, and apart from a single previous injection of vitamin K, which did not seem to have any effect, no other vitamin preparations, iron or other treatment were given, until the red cells were over 6 000,000 and the hæmoglobin was 98%

I am indebted to Dr C H Whittle for the blood counts and Dr W Jacobson for the Price Jones curves

---

IN his annual report for ECCLES Dr J E Spence states that 90 samples of milk were examined under the Sale of Food and Drugs Act of 1938, and 10 of them were found faulty, 49 samples of other foods were taken of which 2 were unsatisfactory, 4 samples of milk were taken from the same source and found to contain between 19 1 and 23 3% added water (appeals to the cow established bovine innocence and human fraud) Fines and costs totalling £22 2*s* were imposed What proportion of the profits of the swindle was refunded by the fine? Two-thirds of the work entailed by the Food and Drugs Acts is now absorbed by milk, and four-fifths of the sophistication detected is practised on milk, because the penalties imposed when a conviction is obtained are so trivial and the profits of the fraud so considerable that milk watering is a highly profitable business and the courts by the smallness of the fines they impose make it almost respectable This is a particularly dangerous form of fraud, for many people are absolutely dependent on milk for their nutrition and may starve for no apparent reason if their milk is watered It has been suggested that the fraud comes near to constructive murder and should be punished as such

Medical Societies

BIOCHEMICAL SOCIETY

AT a meeting of this society on Nov 29 with Prof E C DODDS in the chair, a discussion on the

Mode of Action of Chemotherapeutic Agents

was opened by Dr G M FINDLAY Chemotherapeutic action, he said may be classified as direct or indirect Except in the case of parasites present in the intestinal canal it is essential that the chemotherapeutic drug should be absorbed into the body that it should penetrate to the site where the parasites are acting, and that it should not be excreted or converted too rapidly into an inert form Time must be allowed for chemotherapeutic action and in some cases for the conversion of the compound from an inactive into an active form Once the drug and the parasite have been brought face to face three stages may be distinguished—adsorption, interference with metabolism, and death or such injury to the parasite that it is destroyed by the phagocytes of the host An absorbed chemotherapeutic drug may prevent an essential food factor from being adsorbed or it may cause a breakdown in metabolism by combining with a specific substrate or by competing with an essential cell metabolite for an enzyme or coenzyme One break in the chain of metabolic reactions may rapidly give rise to others Specific immune serum and sulphapyridine do not compete for the same receptor group in the pneumococcus and may therefore enhance one another Parasites may be killed in the body without the aid of phagocytes but usually when a parasite has been damaged it is destroyed by the normal defence mechanism of the host Indirect action produces such changes in their environment that parasites can no longer grow. Physical changes may prevent growth the temperature or the pH reaction may be altered the formation of immune bodies may be stimulated, or the character of the cells may be altered as in the treatment of gonococcal vulvovaginitis in children with œstrin preparations The highly specific action of certain drugs and the no less specific reactions of certain closely allied parasites can be explained by postulating that after adsorption of the compound at the parasite/solution interface the nature of the interference with the metabolism of the parasite depends on what groupings in the molecule of the compound come within the influence of other acceptor groups in the parasite there is thus a multipoint action

Prof ALEXANDER FLEMING said that in 1929 he applied the name penicillin to an antibacterial substance of unknown constitution elaborated by *Penicillium notatum* It is formed in ordinary bacteriological media or in a modified Czapek-Dox medium The action is mainly bacteriostatic and shows a high degree of specificity Pyogenic cocci, clostridia and some other bacteria are sensitive, while the coli-typhoid, hæmophilic chromogenic bacilli and others are insensitive Pathogenic gram-negative cocci (gonococcus, meningococcus and *Micrococcus catarrhalis*) are sensitive while saprophytic varieties—e g, *M flavus*—are insensitive thus differing from the sulphonamides The action of penicillin is not interfered with by substances that inhibit sulphonamides—bacteria, bacterial extracts pus fluids, tissue autolysates, peptones and *p*-aminobenzoic acid Penicillin is non-toxic to leucocytes and animals but in low dilutions it affects the morphology of bacteria and interferes with division Penicillin has been extracted in an impure form by Florey and his associates and this extract is in blood many times more powerful as a bacteriostatic agent than the most powerful of the sulphonamides In vivo, likewise it has been shown at Oxford to have remarkable curative effects in experimental infections of animals and pyogenic infections in man Since penicillin is apparently of a different constitution from the sulphonamides the isolation and synthesis of the pure active principle will open up a new chemotherapeutic field

Prof WARRINGTON YORKE, F R S, described the action of the aromatic diamides which were evolved by Ewins, after it had been shown that Synthalin acted on trypanosomes not by reducing the sugar but by direct toxic action Some aromatic diamidines exhibited a remarkable trypanocidal activity The most active were 4 4′-diamidinostilbene, 4 4′-diamidinodiphenoxypropane and 4 4′-diamidinodiphenoxypentane Cases of kala-azar have now been successfully treated with diamidinostilbene—Indians children in the Mediterranean area, and patients with the Sudanese-variety which was resistant to antimony Babesia infections in dogs were cured by the stilbene and propane derivatives Diamidinostilbene is active against *Trypanosoma congolense,* but replacing the hydrogen atoms of the ethylene group by methyl groups greatly increases the activity against this infection The various diamidines therefore exhibit a considerable specificity of action Study of the phenomenon of drug-resistance may throw light on the mode of action of drugs Drug-resistance in trypanosomiasis has been extensively studied, but little is known of the phenomenon in other protozoal infections Professor Yorke and his colleagues have recently demonstrated drug-resistance in *Babesia canis* infections of dogs and in *Plasmodium knowlesi* infections of *Macacus rhesus*

Dr FRANK HAWKING, discussing trypanocidal substances said that from the phenomenon of drug-resistance four kinds of receptors on the trypanosome are recognised—for arsenicals, acriflavine &c, for parafuchsin, for diamidine compounds, and for Bayer 205 Trypanocidal action comprises fixation of the drug, secondary chemical reactions inside the cell, and death Only about the first process is much known it occurs quickly in a few minutes and is reversible With arsenical compounds, fixation apparently depends on the trivalent arsenic atom linked to a benzene ring Most side-chains prevent fixation but certain ones (-NH_2, -OH) prevent it for the animal cells but not for normal trypanosomes it is compounds with these side-chains which have chemotherapeutic value The receptors of resistant trypanosomes are modified so that they resemble those of the animal cells and thereby therapeutic action is lost Over a wide range, the amount of drug fixed is proportional to the concentration in the surrounding fluid, in the case of acriflavine the partition ratio—the concentration inside the trypanosome divided by the concentration outside—is 8000 for normal trypanosomes 60 for resistant trypanosomes Some fluorescent compounds—e g acriflavine and diamidinostilbene—are concentrated in the blepharoblast and cytoplasmic granules of the trypanosome With Bayer 205 the mode of action is quite different It is not directly trypanocidal in vitro and, although it does seem to form some kind of direct combination with the trypanosomes the amount which is taken up is quite small There is some evidence that it has an opsonin-like action

Sir HENRY DALE P R S, emphasised the importance of having a theory of chemotherapeutic action It was one of Paul Ehrlich's great contributions to the subject to produce a theory which, though it would probably not survive unmodified, gave a tremendous stimulus to research His speculations sometimes appeared more plausible than convincing, but in many cases they eventually proved to be well founded An example was Ehrlich's explanation of the action of certain dyes on infection by trypanosomes as due to injury of the reproductive power of the trypanosomes, without affecting their other vital functions At the time this suggestion seemed artificial and unconvincing but when Dobell and Laidlaw found a method for growing *Entamœba histolytica* in permanent culture in vitro it could be demonstrated that the action of emetine was just of this type Another factor of chemotherapeutic activity which he believed to be important was the "factor of persistence" Effective chemotherapy is usually if not always a war of attrition rather than a Blitzkrieg This seems to be why a quinquivalent arsenical on the one hand or an arseno-compound on the other is a better chemotherapeutic agent than the arsenoxide produced by reduction from the one or by oxidation from the other although the arsenoxide is recognised as the directly parasiticidal agent In the same way sulphaguanidine seems to owe its effectiveness in bacterial dysentery to its poor solubility enabling it to remain in solid form in the intestinal contents an
steady low concentration in contact

promise of which has been

part

her discharge During the first 24 hours 0 75 g of sulphapyridine was given by the mouth Since there was no response 3 c cm of azosulphamide (Prontosil Soluble) was given intramuscularly on May 17 and 0 75 g of sulphanilamide daily until May 22 The daily dose was then halved until May 25 when it was stopped There was considerable improvement and the temperature became normal on May 18 and remained so until the 27th There was no gain in weight, however, and the stools on the 20th gave a strong reaction for *occult blood On the 27th the temperature rose again to* 103° F and an empyema was suspected, but radiography of the chest showed no evidence of lung disease The stools then became more frequent and on May 30 a small amount of *visible blood was passed Vitamin K, 0 5 c cm, was then* given intramuscularly During the next three days the temperature remained up and the general condition rapidly deteriorated On June 2 obvious anæmia was apparent for the first time The baby was then desperately ill with a temperature of 103° F and an almost uncountable pulse It was clearly no use giving iron by the mouth, and blood transfusion was out of the question, so 1 c cm of anahæmin was given intramuscularly Twenty four hours after this injection there was an astonishing change, the whole clinical condition improved, dehydration and diarrhœa became steadily less, and the child began to take her feeds better and to gain weight for the first time This progress continued without interruption until discharge Within a week the stools had become almost normal in number Her weight chart and blood counts are shown in fig 1 By the beginning of July she weighed 7½ lb , seemed healthy in every way and has remained well since without further treatment

BLOOD COUNTS AFTER ANAHÆMIN, 1 C CM , HAD BEEN GIVEN ON JUNE 2

—	June 4	June 21	July 3	July 17
Red cells	2,065 000	3,840 000	5,140 000	6,300 000
Hæmoglobin	54%	62%	84%	98%
Colour index	1 24	0 82	0 82	0 83
White cells	15,600	17,000	24,000	
Polymorphs	6085 (39%)	5400 (32%)	6480 (27%)	
Eosinophils	465 (3%)	340 (2%)	960 (4%)	
Lymphocytes	8425 (54%)	9860 (58%)	14 400 (60%)	
Mononuclears	0	850 (5%)	2160 (9%)	
Myelocytes	465 (3%)	510 (3%)	A few immature polymorphs	
Myeloblasts	160 (1%)			
Normoblasts	1 per 200 white cells	20		
Megaloblasts	6 per 200 white cells			
Primary erythroblasts	5 per 200 white cells			

The blood count findings are shown in the table Price-Jones curves are in fig 2 On June 12 blood films showed considerable megalocytosis and variation in size of red cells , megalocytes 12%, microcytes 1% , mean diameter 7 6 μ On July 10 there were very few megalocytes (1%) and less variation in size of red cells , megalocytes 1%, microcytes 1%, mean diameter 7 3 μ Reticulocytes June 9, 22 5% , June 12, 17 8% , June 14, 17 5% , June 21, 5 6% , July 3, 4 4% , July 10, 1 9% Fragility on July 11 hæmolysis *begins at 0 38%* saline and is complete at 0 26%

Fractional test-meal on June 25 30 c cm 3½% alcohol, no histamine given , 0 036 free hydrochloric acid present in sixth sample Wassermann reaction, negative

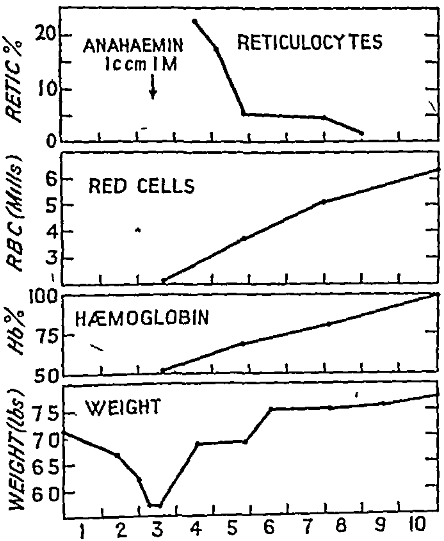

FIG 1

DISCUSSION

In this case the sudden onset of anæmia may have been due to hæmorrhage but was probably partly hæmolytic From its response to treatment it appears to have been due essentially to a temporary lack of anti-anæmic principle or one of its precursers, for the diet was qualitatively unchanged for a fortnight before anahæmin was given until recovery was well advanced The only additional treatment was a single injection of vitamin K four days before the anahæmin, and during this four days progress was rapidly downhill The cause of the deficiency is difficult to explain For the first three weeks of life the diet was certainly deficient in total calories, proteins, vitamins and iron, and as there was also a severe general infection with considerable intestinal disturbance absorption was also probably impaired There was also some loss of blood from the intestinal tract Such a combination in a child of this age is by no means rare but it causes hypochromic anæmia, and not hyperchromic anæmia as in this case Two other possibilities remain—first, that the child started life with deficient stores of anti-anæmic principle, secondly, that treatment with sulphapyridine and sulphanilamide were contributory factors It might also be argued that the recovery was not due to liver extract but was spontaneous, but the striking reticulocyte response is against this The Price Jones curves although they show some degree of megalocytosis, becoming less after treatment, are within normal limits for the age of the patient

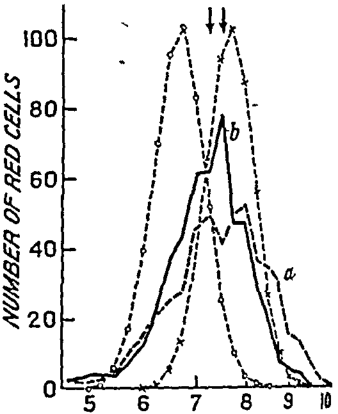

FIG 2

SUMMARY

A case of hyperchromic anæmia in an infant is described in which complete clinical and hæmatological recovery followed a single injection of anahæmin

No qualitative alteration in the diet was made for a fortnight before anahæmin was given or until recovery was well advanced, and apart from a single previous injection of vitamin K, which did not seem to have any effect, no other vitamin preparations, iron or other treatment were given, until the red cells were over 6 000,000 and the hæmoglobin was 98%

I am indebted to Dr C H Whittle for the blood counts and Dr W Jacobson for the Price Jones curves

IN his annual report for ECCLES Dr. J E Spence states that 90 samples of milk were examined under the Sale of Food and Drugs Act of 1938, and 10 of them were found faulty , 49 samples of other foods were taken of which 2 were unsatisfactory , 4 samples of milk were taken from the same source and found to contain between 19 1 and 23 3% added wate (appeals to the cow established bovine innocence and human fraud) Fines and costs totalling £22 2s wer imposed What proportion of the profits of the swindl was refunded by the fine ? Two-thirds of the wor entailed by the Food and Drugs Acts is now absorbed b milk, and four-fifths of the sophistication detected practised on milk, because the penalties imposed when conviction is obtained are so trivial and the profits o the fraud so considerable that milk watering is a highl profitable business and the courts by the smallness of th fines they impose make it almost respectable This is particularly dangerous form of fraud, for many peopl are absolutely dependent on milk for their nutritio and may starve for no apparent reason if their milk watered It has been suggested that the fraud comes nea to constructive murder and should be punished as suc

Medical Societies

BIOCHEMICAL SOCIETY

At a meeting of this society on Nov 29, with Prof E C Dodds in the chair, a discussion on the

Mode of Action of Chemotherapeutic Agents

was opened by Dr G M **Findlay** Chemotherapeutic action, he said, may be classified as direct or indirect Except in the case of parasites present in the intestinal canal it is essential that the chemotherapeutic drug should be absorbed into the body, that it should penetrate to the site where the parasites are acting, and that it should not be excreted or converted too rapidly into an inert form Time must be allowed for chemotherapeutic action and in some cases for the conversion of the compound from an inactive into an active form Once the drug and the parasite have been brought face to face three stages may be distinguished—adsorption, interference with metabolism, and death or such injury to the parasite that it is destroyed by the phagocytes of the host An absorbed chemotherapeutic drug may prevent an essential food factor from being adsorbed or it may cause a breakdown in metabolism by combining with a specific substrate or by competing with an essential cell metabolite for an enzyme or coenzyme One break in the chain of metabolic reactions may rapidly give rise to others Specific immune serum and sulphapyridine do not compete for the same receptor group in the pneumococcus and may therefore enhance one another Parasites may be killed in the body without the aid of phagocytes but usually when a parasite has been damaged it is destroyed by the normal defence mechanism of the host Indirect action produces such changes in their environment that parasites can no longer grow Physical changes may prevent growth, the temperature or the pH reaction may be altered, the formation of immune bodies may be stimulated, or the character of the cells may be altered, as in the treatment of gonococcal vulvovaginitis in children with œstrin preparations The highly specific action of certain drugs and the no less specific reactions of certain closely allied parasites can be explained by postulating that after adsorption of the compound at the parasite/solution interface the nature of the interference with the metabolism of the parasite depends on what groupings in the molecule of the compound come within the influence of other acceptor groups in the parasite there is thus a multipoint action

Prof **Alexander Fleming** said that in 1929 he applied the name penicillin to an antibacterial substance of unknown constitution elaborated by *Penicillium notatum* It is formed in ordinary bacteriological media or in a modified Czapek-Dox medium The action is mainly bacteriostatic and shows a high degree of specificity Pyogenic cocci, clostridia and some other bacteria are sensitive, while the coli-typhoid, hæmophilic chromogenic bacilli and others are insensitive Pathogenic gram-negative cocci (gonococcus, meningococcus and *Micrococcus catarrhalis*) are sensitive while saprophytic varieties—e g , *M flavus*—are insensitive, thus differing from the sulphonamides The action of penicillin is not interfered with by substances that inhibit sulphonamides—bacteria, bacterial extracts, pus fluids, tissue autolysates, peptones and *p*-aminobenzoic acid Penicillin is non-toxic to leucocytes and animals but in low dilutions it affects the morphology of bacteria and interferes with division Penicillin has been extracted in an impure form by Florey and his associates, and this extract is in blood many times more powerful as a bacteriostatic agent than the most powerful of the sulphonamides In vivo, likewise, it has been shown at Oxford to have remarkable curative effects in experimental infections of animals and pyogenic infections in man Since penicillin is apparently of a different constitution from the sulphonamides the isolation and synthesis of the pure active principle will open up a new chemotherapeutic field

Prof **Warrington Yorke**, F R S , described the action of the aromatic diamides which were evolved by Ewins, after it had been shown that Synthalin acted on trypanosomes not by reducing the sugar but by direct toxic action Some aromatic diamidines exhibited a remarkable trypanocidal activity The most active were 4 4′-diamidinostilbene , 4 4′-diamidinodiphenoxypropane , and 4 4′-diamidinodiphenoxypentane Cases of kala-azar have now been successfully treated with diamidinostilbene — Indians, children in the Mediterranean area, and patients with the Sudanese-variety which was resistant to antimony Babesia infections in dogs were cured by the stilbene and propane derivatives Diamidinostilbene is active against *Trypanosoma congolense*, but replacing the hydrogen atoms of the ethylene group by methyl groups greatly increases the activity against this infection The various diamidines, therefore, exhibit a considerable specificity of action Study of the phenomenon of drug-resistance may throw light on the mode of action of drugs Drug-resistance in trypanosomiasis has been extensively studied, but little is known of the phenomenon in other protozoal infections Professor Yorke and his colleagues have recently demonstrated drug-resistance in *Babesia canis* infections of dogs and in *Plasmodium knowlesi* infections of *Macacus rhesus*

Dr **Frank Hawking**, discussing trypanocidal substances, said that from the phenomenon of drug-resistance four kinds of receptors on the trypanosome are recognised—for arsenicals, acriflavine &c , for parafuchsin , for diamidine compounds , and for Bayer 205 Trypanocidal action comprises fixation of the drug, secondary chemical reactions inside the cell, and death Only about the first process is much known , it occurs quickly in a few minutes and is reversible With arsenical compounds, fixation apparently depends on the trivalent arsenic atom linked to a benzene ring Most side-chains prevent fixation, but certain ones ($-NH_2$, $-OH$) prevent it for the animal cells but not for normal trypanosomes , it is compounds with these side-chains which have chemotherapeutic value The receptors of resistant trypanosomes are modified so that they resemble those of the animal cells, and thereby therapeutic action is lost Over a wide range, the amount of drug fixed is proportional to the concentration in the surrounding fluid , in the case of acriflavine the partition ratio—the concentration inside the trypanosome divided by the concentration outside—is 8000 for normal trypanosomes, 60 for resistant trypanosomes Some fluorescent compounds—e g acriflavine and diamidinostilbene —are concentrated in the blepharoblast and cytoplasmic granules of the trypanosome With Bayer 205 the mode of action is quite different It is not directly trypanocidal in vitro, and, although it does seem to form some kind of direct combination with the trypanosomes, the amount which is taken up is quite small There is some evidence that it has an opsonin-like action

Sir **Henry Dale**, P R S , emphasised the importance of having a theory of chemotherapeutic action It was one of Paul Ehrlich's great contributions to the subject to produce a theory which, though it would probably not survive unmodified, gave a tremendous stimulus to research His speculations sometimes appeared more plausible than convincing , but in many cases they eventually proved to be well founded An example was Ehrlich's explanation of the action of certain dyes on infection by trypanosomes as due to injury of the reproductive power of the trypanosomes, without affecting their other vital functions At the time this suggestion seemed artificial and unconvincing, but when Dobell and Laidlaw found a method for growing *Entamœba histolytica* in permanent culture in vitro, it could be demonstrated that the action of emetine was just of this type Another factor of chemotherapeutic activity which he believed to be important was the “ factor of persistence ” Effective chemotherapy is usually, if not always, a war of attrition rather than a Blitzkrieg This seems to be why a quinquivalent arsenical on the one hand, or an arseno-compound on the other is a better chemotherapeutic agent than the arsenoxide produced by reduction from the one or by oxidation from the other, although the arsenoxide is recognised as the directly parasiticidal agent In the same way sulphaguanidine seems to owe its effectiveness in bacterial dysentery to its poor solubility enabling it to remain in solid form in the intestinal contents an

steady, low concentration in contact

mucous membrane Aromatic d

promise of which has been

part

which Professor Yorke has reported, may similarly owe part of their superiority to their limited solubility He suggested as problems whose solution might greatly accelerate advance in parts of the field of chemotherapy the discovery of a method of keeping trypanosomes alive and reproductive indefinitely in artificial culture, and of treating a strain of trypanosomes which had acquired a drug-resistance so as to restore its normal susceptibility

Mr D D Woods, Ph D spoke of the interference of antibacterial agents and essential metabolites This interference may be due to the formation of a compound between the antibacterial agent and the essential metabolite, as between mercury salts and -SH compounds, or to inhibition of an enzyme reaction involved in the synthesis or utilisation of an essential metabolite An example of this is the competitive inhibition by sulphanilamide of an enzyme reaction involved in the further utilisation of *p*-aminobenzoic acid, this inhibition occurring by virtue of the chemical relationship of sulphanilamide and *p*-aminobenzoic acid The latter has been isolated from natural sources and is a growth factor for *Clostridium acetobutylicum* and higher organisms Working on this hypothesis, the following substances, all chemically related to a known essential metabolite (shown in parentheses), have been found to have some antibacterial activity—pyridine-3-sulphonic acid and amide (nicotinic acid and amide), aminosulphonic acids (analogous aminocarboxylic acid), sulphonic acid analogue of pantothenic acid (pantothenic acid), indole-3-acrylic acid (tryptophane), barbituric acid (uracil)

Mr H McIlwain, Ph D, said that an organism which is deprived of the use of enzymes or metabolites by various types of interference is nutritionally more exacting than in its normal state *Bacterium coli* and *Streptococcus hæmolyticus*, inhibited by acriflavine components, require for further growth two types of material not normally required Type 1 is best replaced by nucleotides, type 2 by a concentrate of amino-acids, but partly by phenylalanine In the presence of type 2 compounds but not without, artificial hydrogen carriers are further active against inhibition of *Bact coli* Type 1 compounds form complex salts with acriflavine components The inhibitors probably inactivate enzyme systems of which type 1 compounds are essential parts, of which type 2 compounds are substrates or products, and of which some can be replaced by the hydrogen carriers

Mr W H Linnell, Ph D, described the relationship between chemical constitution and bactericidal action in certain amino acridines Among the isomeric diamino-acridines, 1-amino group causes complete loss of bactericidal activity and reduces toxicity, a 2-amino group increases activity and this is further enhanced by another amino group in the 2-, 3-, 4- (in the other ring), or 5-positions, accompanied by increased toxicity in the case of a second 2- substituent When two 3-amino groups (= 3 7) are present, activity is moderate, but the 3 8 diaminoacridine (= 2 7) is as active as proflavine but less toxic A 4-amino substituent confers small activity while position 5 is highly active but probably leads to increased toxicity Albert has shown that similar differences in activity exist among the five isomeric monoamino acridines, their activity paralleling their strength as bases and their partition coefficients between oil and water The corresponding acridones are inactive, as are certain amino derivatives of 5 10-dihydroacridine and of iminodihydroacridine, suggesting that the intact acridine molecule is necessary

Mr L G Goodwin, B Sc, said that the uncertain action of antimony in protozoal diseases, of which the resistance of Sudanese kala-azar to antimony is an example, is an added difficulty in investigating its mode of action The active form of antimony may be the stibinoxide grouping, but while this is probable in trypanosome and schistosome injections it is unlikely in leishmaniasis where quinquivalent compounds are the most effective and massive dose therapy is successful Excretion of antimony after doses of the quinquivalent compounds or of stibophen is much more rapid than with tartar emetic There is some indirect evidence that the rapidly excreted fraction of the drug passes through the body unchanged Both direct toxic action on parasites and stimulation of the hosts' defence mechanisms are produced by antimonials Increased phagocytosis may be of primary importance in leishmaniasis, though histological work on the spleens of infected hamsters injected with a quinquivalent antimony compound suggests some degree of direct action

Mr E Chain, Ph D, described the chemical and physical properties of penicillin in relation to its bacteriostatic action It is a strong acid with two or a multiple of two acid groups A purified barium salt gives a carbon content of 55% and an H content of 6 3% only C, H and O are present in the molecule Methoxyl groups cannot be detected but two hydroxyl groups are present The dried Ba salt of penicillin keeps indefinitely and in watery solution is most stable between pH 5 and 7 With heavy metals, except ferric iron, it forms water soluble salts The antibacterial action is lost by oxidation with hydrogen peroxide and potassium permanganate

Mr E P Abraham, Ph D, said that the instability of penicillin necessitated three methods of purification dependent on distribution between solvents, adsorption and reduction The crude barium salt obtained from an amyl-acetate extract of the medium has an activity of 15-25 units per mg Distribution between water and ether at pH 2 and pH 6, adsorption of impurities by charcoal, and chromatographic analysis on alumina yield a light yellow barium salt with an activity of about 150 units per mg On reduction of this material in neutral solution with aluminium-mercury couple the remaining pigment is adsorbed by alumina The white barium salt obtained from the supernatant has an activity of 240 units per mg It completely inhibits staphylococcus in a dilution of 1 in 5,000,000, and partially in a dilution of 1 in 16,000,000

Mr F R Bradbury, Ph D, has studied the behaviour of sulphanilamide, *p*-aminobenzoic acid and chemically related compounds, aniline and sodium benzenesulphonate, at the surface of *Bact coli* by electrokinetic methods The shapes of the curves relating variation of mobility with time of contact for sulphanilamide and *p*-aminobenzoic acid are quite different from those of the curves for aniline and sodium benzenesulphonate The curves for sulphanilamide and *p*-aminobenzoic acid are similar, suggesting that the two compounds behave in a like manner at the bacterial surface

Prof A St G Huggett said that dyes such as chlorazol sky blue FPS (Chicago blue) and chlorazol fast pink BKS are excellent anticoagulants Structurally they resemble afridol violet from which Bayer 205 is derived, they have a trypanocidal action while Bayer 205 has an anticoagulant action The dyes act at two points in the clotting mechanism, as antikinase and as antithrombin Their antienzyme action in blood clotting may have an analogy to their mechanism as trypanocidal agents

---

SOCIETY OF M O H 's

At a meeting of the Fever Hospital Medical Service Group of this society on Nov 14, a discussion on

Fever Hospitals and Pathological Services in Post-war Planning

was opened by Dr H Stanley Banks (L C C) who thought that fever hospitals as well as general hospitals should be regionalised Modern fever-hospital work requires the equipment of a general hospital—e g, first class laboratory service, X-ray and physiotherapy departments and operating-theatre Wards for the general sick can be a success in fever hospitals In future, fever units and general units could be combined under one administration Over 80% of fever hospitals outside London have less than 50 beds, and about 55% less than 20 beds Many of these small hospitals should be closed or linked up with others It is important to determine the best method of administration of a regional authority The usual local-authority method by which a chief medical officer appointed by the authority is responsible for both the management and medical direction inevitably leads to a centralised bureaucracy This may be effective for a time by improving the backward units but soon produces atrophy at the periphery, and medical progress depends on initiative at the periphery as well as support from the ntre There should be a proper balance of power and sponsibility between the two, which might be chieved by leaving medical direction to local and gional medical committees of senior staff The egional committee could make itself responsible for onveying medical advice and direction to the authority, y the use of a whole-time staff if necessary Some such cheme of decentralisation of medical direction is essential o preserve the vitality of a hospital service

Dr L J M Laurent (L C C) suggested that voluntary ospitals, owing to increasing grants from the state, are ound to come under state control They enjoy a emi-independence which helps medical progress but does not further mutual support Municipal hospitals under the management of local authorities have become as efficient as voluntary hospitals but labour under a ighly centralised administration Any future scheme of hospital planning should avoid the disadvantages of both and the perpetuation of a dual system of hospitals The creation of a regional authority to control both kinds as equal partners would be a step in the right direction Modern fever hospitals approximate so much to general hospitals that they should come under the same authority Small fever hospitals should be replaced by larger units serving adjacent areas The large fever hospitals as a result of the war are now treating cases of tuberculosis, chronic sick and senile patients pneumonias, skin disorders and casualties, besides cases of notifiable disease After the war a diminution of infectious diseases is to be expected, and the beds left vacant could continue to be used for these cases To meet the needs of medical education fever hospitals should be allowed to receive patients from larger areas than at present An infectious-diseases block attached to a general hospital would benefit both sections

Dr A A Cunningham (L C C) thought that a good deal of the open ward accommodation in large fever hospitals could be made available for general medical and surgical cases This practice was begun in London before the war The head of a hospital should be a medical superintendent, not a layman but there should be well-paid posts for good clinicians Teaching hospitals should have a voice in the appointment of those who train students in infectious diseases

Dr J E McCartney (L C C) said that a pathological service must provide for all classes not only for hospitals but also for medical practitioners and public-health work. As the laboratory must be near the patient, the technical work should be decentralised as much as possible, but supplies, equipment, and conditions of service should be standardised as far as possible The country would be divided into regions, and the regions into groups each under a pathologist working in the main laboratory of the group, which would be similar to a L C C group laboratory According to need there would be sub-group laboratories staffed by assistant pathologists, or where work was insufficient, a technician would be employed No separate public-health laboratories would be provided but the medical officer of health would be in touch with the group pathologist in his area who would organise all pathological work , a mobile laboratory staffed by personnel from less busy parts of the region would be sent to any epidemic The work of the region would be coordinated by a regional pathologist who should not be a whole-time administrator but attached to or in charge of a laboratory, and his work would be mainly technical All regions would be coordinated by a director of pathological services Technical and administrative sides would be run by a committee consisting of regional pathologists and administrative staff—e g , for personnel, finance, buildings London would be organised on similar lines to suit its requirements There should be full cooperation with university teaching departments, many of which would be the main regional laboratories Research would also be coordinated The organisation of supplies would be on the lines of the L C C centralised system which supplies not only its own laboratories but also the Ministry of Health sector laboratories in London The L C C pathological service, now functioning as a regional laboratory service, might become the basis of a national one

Dr Robert Cruickshank (L C C) thought that the association of laboratory services with infectious diseases hospitals needs to be developed, for laboratory help is essential in the diagnosis treatment and control of most infectious diseases Besides, a laboratory on the spot helps to maintain the standard of work in the hospital and encourages coordinated investigation and research To do this the laboratory staff must not be overburdened with routine work, and the intellectual calibre of the personnel should be high In the past, the clinical pathologist has often been regarded as inferior to his colleagues in the teaching and research departments but with full-time adequately paid posts and encouragement of research clinical pathology should be able to attract the best brains The laboratory doing the bacteriological work of the fever hospital should also do the public-health bacteriology of the surrounding area Such an arrangement is specially desirable in London where the liaison between the borough M O H and the local isolation hospital is not as close as it might be Field epidemiology, at present rather neglected would also be encouraged by a system of regional laboratories such as the L C C had established in London

Dr R A O'Brien (Beckenham) was of the opinion that no scheme for the future of the pathological services need look further than the L C C group system for a plan on which to build

Dr E C Benn (Leeds) agreed that hospital regionalisation is inevitable Each part of the country has its own problems and one of the major obstacles to be overcome is local prejudice Full pathological services should be available to every hospital, but small units attached to small hospitals are to be avoided in the interests of economy

Dr A G Troup (Willesden) spoke of general hospitals he has visited in Austria and Czechoslovakia with successful fever sections The admission of ordinary medical and surgical cases to isolation hospitals is safe from the cross-infection point of view and Dr Troup described his experience of this at the Willesden Isolation Hospital Fever hospitals must be considered in any scheme in order that all available beds can be used for the maximum benefit of the community In London the sector system might form the basis on which to found the post-war scheme The better and more modern fever hospitals should be enlarged and the others used for a different purpose or closed The Local Government Act of 1929 and the Public Health Act of 1936 suggested this but no progress has been made owing to the absence of compulsory powers

Dr Fred Grundy (Luton) preferred to substitute for Dr McCartney's " mobility of personnel," a flexibility of personnel, for pathologists should remain long enough in a laboratory to get to know the local doctors No isolation hospital should have less than 200 beds so that each should carry at least one resident medical officer Local government areas should be amalgamated under existing legislation or rearranged But the future of the treatment of infectious diseases will be found in the linkage of cubicle blocks and special wards with general hospitals, or possibly, with children's hospitals Planning should take into account the need for improvement in the training of nurses

Dr D V Hague (Yeovil rural district) thought that separate infectious disease hospitals are unnecessary Greater efficiency would be found in a fever unit of a large general hospital, for there would be greater opportunities for consultation and treatment, better education of medical students in fevers, and all nurses would get fever and general training With competent fever-trained staff the disadvantages are negligible Some of the present isolation-hospital buildings might be used as children's hospitals where the school M O might act in a clinical capacity to the benefit of the patients and the school M O himself, who has far too little experience of sick children If regional control is adopted, there should be some local autonomy, and mechanism for the regular expression of opinion on local conditions to the regional board

Dr William Gunn (L C C) did not think that epidemic diseases will subside much after the war Under a statutory organisation the smaller voluntary hospitals would no longer be run as nursing-homes for the benefit of the consultants The best unit in a hospital system would be a large hospital centre with a minimum of 1000 beds and general and special departments of all kinds A workable scheme on these lines, the "Walton plan"-has been worked out

Dr C A McPherson (Chertsey, and Walton and Weybridge urban district) said that the lack of a pathological service is one of the chief disadvantages of a small isolation hospital The provision of this by the E M S has been of the greatest value X-ray facilities are also needed perhaps as mobile regional units In some provinces in France general hospitals successfully provide treatment for tuberculosis and infectious disease, and have health departments which administer the other public-health services

Dr R W Tannahill (Waltham joint hospital board) regarded 250,000 as a population for which it is economic to provide an infectious-diseases hospital, and where necessary districts should be combined Such a combined *authority could support a full-time resident medical* officer The infectious diseases hospital should be able to admit all infectious diseases in the area whether notifiable or not and this is possible only in the larger units Many small hospitals admit only scarlet fever and diphtheria Infectious wards in general hospitals have been in operation in other parts of the world for many years It is an advantage to have the services of the consultant staff and of the pathological department available for infectious cases and the resident medical and nursing staffs learn much from a spell of duty in the infectious wards Existing fever hospitals could be attached to a large general hospital for these services

Reviews of Books

Integration of the Personality

C G Jung London Kegan Paul, Trench, Trubner and Co Pp 313 15*s*

Dr Jung is well read in esoteric subjects, but his learning seems too heavy *for him in this work The book is* overloaded with quotations and references and unless its readers have a liking for statements in which abstruse semantics are blended with a subfusc mysticism they will not penetrate Dr Jung's meaning The six lectures composing the book are concerned with individuation, by which is meant "the psychological process that makes of a human being an individual" The earliest section deals with the animus and the anima, familiar in Dr Jung's previous writings as primordial figures, archetypes located in the collective unconscious A case is described, with an illuminating account of how Dr Jung deals with the symbolic material in patients' drawings, and in a later chapter the dreams of a patient are interpreted on rather gnostic lines The psychology of alchemy is examined at length in chapter 5, and the final chapter contains some opinions about the modern need for a leader who has decided to follow the law "that comes from within He has been called away from the all-powerful, all-oppressing psychic life that is his own and his people's affliction . With the very decision to put his own way above all other ways he has already in large part fulfilled his liberating vocation He has cancelled the validity of all other ways for himself —he has placed his law above all conventions" Dr Jung delivered the lecture in which this passage occurs in 1932, but he can hardly have foreseen how canonical this bit of Fuhrer-doctrine would soon become, it was, however, well placed after the chapter on alchemy, since the futile arm of alchemy was to transmute dross

It Passed Too Quickly

Air Vice Marshal Sir David Munro, M A, LL D St And, M B Edin London Routledge Pp 304 15*s*

This work, suffused with personality, is the story of a small boy in an Eton suit arriving at St Andrews University in a cab from Leuchars at the age of fourteen as an undergrad, and returning nearly fifty years later to the same station with an escort of planes, to be drawn from thence by students in triumph in an open carriage after his election as rector of his old university What happened to him in the interval is displayed with staccato zest He left St Andrews with his M A degree to finish his medical career in Edinburgh, working under Caird, R J A Berry, Schäfer, Greenfield, Littlejohn, Byrom Bramwell—what a galaxy Then came entry into the I M S at the time of the South African War, and work at Netley under Sir Almroth Wright and Leishman Then India, to one frontier post after another in succession, a period which allows of rapid little of officers, tribesmen, patients, hospitals, marches the Guides, the Delhi Durbar and Curzon pig-sticking and big-game hunting After three or years on the military side came marriage and a to the "civil" and life in Calcutta The I M S was then in its heyday "We were Harley Street and the universities in one Museums, jails, botanical gardens, marine surveyships, even the Mint had I M S officers, and held all the teaching appointments in the medical schools The author had his fair share of these respo he thought he was in civil employ for life

And then unexpectedly came the war of 1914–18, *recall to service again* home to England, hospital ships in the channel for Indian wounded, idle days in the Isle of Wight, a sudden order East again, Basra, "Mespot"—the now almost forgotten story of the medical muddle—Gertrude Bell, Sir William Willcox, Sir George McMunn, Sir Matthew Fell Again change Egypt, Allenby, lines of communication the great advance, the armistice Then home again to England, and transfer from the I M S to the newly formed Air Force Medical Service of which a few years later he was to become director-general After that, secretary to the Industrial Health Research Board, where the tale ends Among the great variety of interest, the many wise and witty comments on life in general, on medical education and on sport especially hunting of which the author is a devotee the reader must browse for himself A full life is recorded here, a stimulus to all who read it

Contraception

(5th ed) Marie Carmichael Stopes, D Sc Lond London Putnam and Co Pp 459 15*s*

This book reflects the personal views and character *of a pioneer It contains information* which must have taken many years to collect, but is not an unbiased statement of the present state of contraceptive technique Why Dr Stopes elected to end her history of the birth control movement with a party at the Ritz celebrating the tenth birthday of the original clinic is obscure, a lot has happened since 1931 The birth of Dr Abraham Stone's admirable *Journal of Contraception* (now *Human Fertility*), the work of the Birth Control Investigation Committee and the Family Planning Association and its medical subcommittee are unnoticed, the references to modern work on spermicides are sketchy, and no mention is made of Dr J R Baker's recent work on them, of Dr H Carleton's study of local effects of various chemicals, or of the clinical and laboratory work done in America

Essentials of Dermatology

Norman Tobias, M D, senior instructor in dermatology, St Louis University London J B Lippincott Company Pp 497 28*s*

More useful information is crammed into this small book than there is in textbooks many times its size—hardly any redundant matter and plenty of good photographs which may account for the rather high price Here and there the brevity of the discussion leads to some confusion, as when under lupus erythematosus it is stated that gold is a useful drug without mentioning what type of gold should be used or how it should be administered Similarly under secondary exfoliative dermatitis, except for the illustration, no mention is made of dermatitis due to N A B or gold salts, surely two of the most important causes of this disease An important omission is that streptococcal tonsillitis may be and often is the cause of erythema scarlatiniforme Not all agree that granuloma annulare responds to treatment with Fowler's solution or that 606 is better than 914 in the treatment of syphilis Dermatologists in this country are satisfied *that in the treatment of ringworm of the* scalp X-ray epilation is the treatment of choice and not, as Dr Tobias suggests, to be reserved for intractable cases The chapter on eczema, is one of the best expositions on the subject to date, but is it for the benefit of the patient or doctor that subjects of intractable atopic eczema are to be advised to move to another part of the country?

THE LANCET

ONDON, SATURDAY, DECEMBER 20, 1941

OLLECTION OF INVASION CASUALTIES

AUTHORITIES have been urged to cooperate with h other so that the combined machine for the lection of casualties shall work as smoothly as sible if we are invaded There are three main emes in operation, and each of them possesses aid-sts of different capacities, all of which, together h all the ambulances, are to be available for both ilian and military casualties An attempt is now ing made to weld these services into one and to range their aid-posts on a network plan, which shall ow the least specialised to be ranged around those more complexity, and these again around the neral hospitals

The first or lowest class of aid-post may be either a tachment aid-post of the R A M C (consisting of ne or two first-aid men and a small satchel of essings), a civilian first-aid point, a Home Guard sualty collecting post, or a wholly unofficial private ouse or factory which may chance to have a certain mount of equipment Walking casualties are xpected to find their way to such points as these, nd Home Guard stretcher bearers will also be expected to carry their charges there, but civilian tretcher cases are to be taken by ambulance direct rom the place at which they are injured to some post n the second or third class The posts of this first class will not have a doctor in regular attendance Between the first and second class of posts there comes an intermediate class which includes advanced dressing stations of the R A M C, regimental aid-posts of the Home Guard and up-graded points of the civil services The precise function of these units is likely to vary with the needs of the moment Their equipment is simple and their staff extremely small The second main class of aid-post comprises main dressing stations of the R A M C, first-aid posts (mobile or fixed) of the civil services, and some of the smaller hospitals These are intended for the treatment and temporary accommodation of cases which do not need specialist surgical treatment but are yet so severely injured as to need inpatient care or to be sent home to bed by ambulance These posts will also deal with walking cases from their own vicinity or cases brought in from a distance without stopping at any lesser post The third and last form of medical aid is to be given at casualty clearing posts of the R A M C or at fully equipped military or civilian hospitals In so far as these may prove to be too near to the battle zone for reasonable safety, their patients will be cleared as soon as possible after operation by Green Line ambulance or hospital train to suitable refuges in remoter areas

These three classes include most but not all of the recognised posts The normal course of a stretcher case from the time of wounding until he reaches hospital will vary according to whether he follows the R A M C, the Home Guard or the civilian route of vacuation The fact that he follows any particular ute does not imply that he is either a soldier or a vilian, each may follow any of three routes

The wounded soldier or the wounded civilian in a military area will be picked up on the battlefield by regimental stretcher bearers and carried to the nearest post of class 1 In the case of the Army this will usually be an advanced dressing station or a regimental aid-post Here he will be looked after until it is possible to load him on an ambulance The ambulance will convey him, according to his needs, to a post of class 2, direct to a hospital, or perhaps an ambulance train for further transport away from the scene of action Having received the best attention possible at the second class post he will if necessary be sent on to hospital This will either be some special hospital—say for fractures or head cases—or a general hospital

2 The Home Guard stretcher case will be picked up on the battlefield by H G stretcher bearers and carried to any post of class 1 If this is a H G casualty collecting post, the Home Guard must then establish contact with the civilian control centre and look after the wounded until ambulances arrive to take them away Home Guard responsibility will then cease and casualties will follow the civilian route of evacuation

3 The wounded civilian will get into touch with the air-raid warden or the police who will in turn get into touch with the control centre This will send out (if possible) both a first-aid party and an ambulance or ambulances The wounded will then be taken to a post of the second class, to one of the intermediate class, or to a hospital according to the needs of the case as assessed by the first-aid party If a number of civilian casualties occur at one spot the control centre may send out a mobile first-aid post with orders to open up in some convenient building and deal with the cases on the spot

These are the main types of post and the main lines of evacuation at present planned, but their harmonious coordination is hampered by several factors Many people suppose that it will not be possible to put ambulances on the road in invaded areas for periods which may be as long as a week Some posts—for example the up-graded points now being established—are required to have accommodation and rations for a week while others, notably the Home Guard posts and ordinary civilian points, are established on the understanding that ambulances will always be available and that they will not be called on to retain patients Until it is generally agreed whether it is wise to depend on immediate clearance by ambulance no satisfactory cooperation is possible If it should prove that ambulances are delayed for periods ranging from 24 hours to a week all posts of the first class would have to provide hasty and probably unsatisfactory accommodation, dressings and food In a settled and well-populated country it ought not to be necessary to depend on last minute improvisations to this extent A second obstacle to cooperation is the present distribution of medical man-power As at present arranged, the civilian services claim to have the first call on all medical men, including those of the Home Guard but not those of the R A M C, even if temporarily idle This claim includes the right to keep medical officers at duty points—such as a garage housing a mobile ambulance—even if there is no work for them to do and even if, as Home Guard or civilian doctors, there may be great need for them elsewhere So long as one Service makes a claim of this sort there is bound to be a serious wastage of medical man-power and this wastage we can ill afford What is needed is some form of clearing house for medical men under the control of a commission representing all three Services, which shall get to work before the emergency comes and continue to operate in time of invasion A third difficulty arises because there is no agreement about decentralisation and dispersal of ments of all kinds A workable scheme on these lines, the "Walton plan" has been worked out

Dr C A **McPherson** (Chertsey, and Walton and Weybridge urban district) said that the lack of a pathological service is one of the chief disadvantages of a small isolation hospital The provision of this by the E M S has been of the greatest value X-ray facilities are also needed perhaps as mobile regional units In some provinces in France general hospitals successfully provide treatment for tuberculosis and infectious disease, and have health departments which administer the other public-health services

Dr R W **Tannahill** (Waltham joint hospital board) regarded 250 000 as a population for which it is economic to provide an infectious-diseases hospital and where necessary districts should be combined Such a combined authority could support a full-time resident medical officer The infectious-diseases hospital should be able to admit all infectious diseases in the area whether notifiable or not and this is possible only in the larger units Many small hospitals admit only scarlet fever and diphtheria Infectious wards in general hospitals have been in operation in other parts of the world for many years *It is an advantage to have the services of* the consultant staff and of the pathological department available for infectious cases and the resident medical and nursing staffs learn much from a spell of duty in the infectious wards Existing fever hospitals could be *attached to a large general hospital for these* services

Essentials of Dermatology

Norman Tobias, M D, senior instructor in dermatology, St Louis University London J B Lippincott Company Pp 497 28*s*

More useful information is crammed into this small book than there is in textbooks many times its size—hardly any redundant matter and plenty of good photographs which may account for the rather high price Here and there the brevity of the discussion leads to some confusion, as when under lupus erythematosus it is stated that gold is a useful drug without mentioning *what type of gold should be used* or how it should be administered Similarly under secondary exfoliative dermatitis, except for the illustration, no mention is made of dermatitis due to N A B or gold salts, surely two of the most important causes of this disease An important omission is that streptococcal tonsillitis may be and often is the cause of erythema scarlatiniforme Not all agree that granuloma annulare responds to treatment with Fowler's solution or that 606 is better than 914 in the treatment of syphilis Dermatologists in this country are satisfied that in the treatment of ringworm of the scalp X-ray epilation is the treatment of choice and not, as Dr Tobias suggests, to be reserved for intractable cases The chapter on eczema, is one of the best expositions on the subject to date, but is it for the benefit of the patient or doctor that subjects of intractable atopic eczema are to be advised to move to another part of the *country ?*

e patient was then studied and the emotional signi- ance of his illness was assessed as far as possible , st before the round his respiration, pulse-rate and ood-pressure were taken During the presentation his case he was watched for changes in facial expres- on, blushing, pallor, restlessness, laughter or crying etween one and three hours afterwards he was inter- iewed again and his anxiety was judged , he was en asked to define medical terms used at the bedside he patients were adults except for 4 girls between he ages of nine and twelve and 1 boy of thirteen heir ailments included infections deficiency diseases, etabolic disorders, neoplasms, degenerations and sychogenic illnesses The preliminary examination howed that 29 men and 30 women had little, 9 men nd 16 women much, anxiety associated with their llnesses , in 2 women the illness was predominantly eurotic , and there was confusion or a variable degree of awareness, in 11 men and 3 women

The demonstration produced no severe emotional trauma in any of the patients Nearly all were grateful for the preliminary explanation There was, of course some anticipatory anxiety. which reached its peak when the group entered the ward and came to the bed, and then subsided , 24 patients, including both the neurotics admitted to feeling uneasy and tense, 12 of these belonged to the group of 25 who were already anxious about their illness and 7 to the group of 14 who were confused Only the two neurotics showed significant changes in pulse and blood-pressure Repetition of the history distressed 13, especially when this was the occasion for learning unfamiliar facts One youth discovered for the first time that he had had fits during the course of his illness and was greatly disturbed , a woman disliked a reference to a previous attempt at suicide , a man was wounded by the description of his ill-fitting shoes as "second-hand" The physical examination only annoyed 7 Some were embarrassed by being made to undress before an audience, and others were troubled because attention became focused on aspects of the disease which—to them—had previously seemed trivial Thus a boy with diabetes and nephrosis became anxious when his heart was scrupulously examined "I haven't got heart disease, too, have I ?" he asked Group laughter worried nobody , usually the patients could share the joke and joined in Of 69 patients who remained for discussion of their cases 11 would rather have been removed, most of them because they felt tired or hungry or were in pain Of 31 patients who were removed 16 would have preferred to remain , so that on the whole curiosity outweighed discomfort Divergent opinions in the group seem only to have impressed patients with the thoroughness with which cases were being studied which belies the oft-told story of a patient who having listened to the unanimous opinion of a group of dressers that his tumour was benign and the honorary's ' I propose to operate at once," got out of bed and went home, remarking "No, you don t ! '

Definitions of medical terms by patients showed how wide interpretation may be of the mark Neoplasm, mitosis metaplasia and metastasis fortunately had no meaning for any patient Shock, stroke, and paralysis were used interchangeably Neurotic was defined as "nuts ' or ' due to imagination," but "nervous breakdown" was accepted as a respectable consequence of overwork "Degenerative' was interpreted as implying moral decay, and ' prognosis ' meant ' no hope " for some This section of the investigation has a special interest reminding us how constantly we should be on guard against the use of terms which may spread not only alarm and despondency but undue hope Thus it is common experience that for most patients the word ' progressive means a disease which will get progressively better , that "Graves's disease' carries the most gloomy interpretation ; and that many a mother has been convinced that she must face a breech delivery from the use of the term "occipito-posterior ' On the whole, however, Dr ROMANO has shown that though patients may grumble a bit they are not unduly upset by ward rounds , and that a little extra care and vigilance will serve to allay what anxiety such experiences produce.

Annotations

FEEDING THE MINER

SINCE attention was last drawn in these columns to the need for supplementing the rations of workers engaged in heavy industries, such as coal-mining steps have been taken to make supplementary rations available to miners The Ministry of Food has been anxious to secure that this supplementary food is in fact consumed by the miners themselves, and it has therefore been considered necessary to make the issue at the mines concerned There are several possible methods of making an issue of this kind—by the provision of packets of food containing pies meat patties &c which can be given to the miner at the pithead for consumption either underground or when he goes home by the provision of hot meals at the surface on completion of the working shift, or by sending suitable hot food down to be consumed underground during the mid-shift break Each of the first two methods has been adopted fairly widely with what success it is not yet possible to say The first can at best provide a better cold "piece," which is obviously not ideal and it may well be easiest to provide a hot meal in a surface canteen at the collieries that have already been equipped with pithead baths through the activity of the Miners Welfare Commission Mr David Robertson, M P , favours the third method—a hot meal underground in the middle of the miner s working spell. The difficulties of this must vary a great deal from colliery to colliery, but it should not be impossible to serve hot meals under these conditions at several points for comparatively small groups of men Many hospitals use thermos-like containers capable of carrying ample food for twenty or thirty patients and keeping it at constant heat for a time amply sufficient to meet mining circumstances It may be that any system of distributing food underground raises difficulties in relation to payment and so on, and that the only practicable solution may lie in sending down individual containers with one man's ration in each Even that should not be impossible, with a little ingenuity on the part of the makers of containers Experiments have been carried out at a Midlothian colliery which promise good results in this distribution of hot food underground and the men in that colliery are said to favour the method Mr Robertson lately demonstrated some containers to members of the House of Commons and it seems probable that this system will be tried out on a more extended scale It will be interesting to see whether developments along these lines do anything to remedy the notoriously high incidence of gastritis among coalminers Efforts of this sort can scarcely fail to improve the miner s lot and must in the long run contribute to efficiency and output medical equipment and first-aid workers It must first be agreed, of course, whether circumstances will or will not compel the dispersal of casualties and whether concentration of casualties in defended towns and other danger spots should be permitted There are bound to be differences of opinion and no official decision will command universal approval, but these points should at least be discussed and a line of action should be agreed on by the heads of all three Services Otherwise the Services themselves can never cooperate in a way to command the confidence of the public

THE MAN IN THE IRON LUNG

The Drinker type of respirator, so beloved of public fancy, has only a limited use in this country where widespread epidemics of anterior poliomyelitis are rare There are patients, however, whose lives depend on its use, and their management calls for highly skilled medical supervision and nursing In America such cases are more common **Schmitt** and **Seldon**,[1] of the Mayo Clinic, discussing practical points in management, say that negative pressure should not exceed 20 cm of water, and that positive pressure is needed only when the patient is being taught to cough Negative pressure should be increased to 25–30 cm of water for a few minutes every four hours, to keep the costochondral joints from getting stiff The respiratory rate is kept at 18–20 a minute, and rate and pressure should be the lowest possible to keep the patient comfortable and of a good colour His head is kept lower than his feet, making an angle of some 20° with the horizontal, and mucus and secretion draining into the throat as a result of this posture are aspirated by gentle suction Portholes in the respirator make it possible for ordinary nursing care to be given without removing the patient, but for any complicated measure it may be necessary to take him out If the respiratory muscles are not completely paralysed he may be able to breathe without mechanical aid for a few minutes, otherwise if the machine is opened respiration must be maintained in some other way, and **Schmitt** and **Seldon** have devised a simple technique of giving oxygen through a face mask and bag When the machine is stopped, or open, the mask is applied, and the bag is squeezed rhythmically 18–20 times per minute In this way the patient is able to remain out of the machine long enough for essential nursing and medical attention to be carried out thoroughly

Between 400 and 500 patients suffering from poliomyelitis were treated in respirators in the United States last year Two-thirds of them had bulbar paralysis with pharyngeal paralysis, and two-thirds of these died **Wilson**,[2] **Schmitt** and **Seldon** agree with the English findings that better results may be obtained in bulbar paralysis from measures directed to maintaining the patency of the air-passages than from treatment in the respirator **Wilson** mentions the use of tracheotomy in selected cases He says that the respirator is clearly indicated only when the respiratory difficulty is due to intercostal or diaphragmatic paralysis and that a third of the 400–500 cases fell into that category, of which less than 20% died Although it is sometimes questioned whether the use of the respirator is justified for patients who, if they survive, may be so severely paralysed that their lives will be of little value to themselves or **Wilson** points out that at the time when the use respirator must be begun it is impossible to the future degree of paralysis and thus every should be given his chance of survival and r He emphasises the importance of instituting ment in the respirator early if there is evider weakness of the intercostal muscles and diap in the belief that the weakened muscles can be and protected by treatment in the respirator and possibly less strain put on the damaged anterior cells He suggests that the patient should examined for weakness of the neck and shou muscles, which is invariably associated with costal and diaphragmatic paralysis, and he bel that the respirator should be used long before cyanos dyspnœa and air-hunger appear **Schmitt** **Seldon** give as the chief indications for placing patient in the respirator restlessness, monosyllab speech, increased respiratory rate and a vital capaci of less than 250 c cm of air

In America it is difficult to make the ideal ear decision for treatment in the respirator because the are not enough machines, and there it is hoped th some cheap, readily portable and effective respirat perhaps of the cuirass type, will be developed T position is different in Britain where Lord **Nuffi** has ensured that respirators are available in almo every hospital

WHERE THE WARD ROUND RUBS

Patients probably cared little enough for t attentions of medical students even before Martial, the first century A D, wrote

> Languid I called on you, Symmachus, quickly you heard n
> Quickly you came with a hundred raw students behind
> They earnestly pawed me all over with hands like the arct
> I was free from the fever before, but now—by Apollo !
> I'm burning

Certainly this restive spirit in the clinical material h not changed since Repeated examinations are n the only harrying part of the business the patie may be perturbed by other aspects of the ward rou —by anticipation, by the conflicting opinions of t examiners, or by his own misinterpretation of so technical term which he is too frightened to ask abo Dr **John Romano** has investigated[1] 100 unselect patients at the Peter Bent Brigham Hospital befo during and after the Saturday morning teachi round and has shown some of the ways in which t patient may be unwittingly dismayed On th rounds one or two patients from each of the fo medical wards are presented to a group of 50- people, including members of the staff, visiting d tors, students and nurses The patient's bed is plac in the centre of the ward, the history is given, t patient is questioned and examined, and finally case is freely discussed The occasion thus has important publicity and the patient may have to w for a period ranging from a few minutes to an ho for the ward round to reach him The patie investigated were all prepared for the experience the senior house-officer who told them, on the d before the round, that they were being shown to large group of physicians because their cases present difficulties which would be better understood a treated after general discussion The personality patient was then studied and the emotional signi- nce of his illness was assessed as far as possible t before the round his respiration, pulse-rate and od-pressure were taken During the presentation his case he was watched for changes in facial expres- n, blushing, pallor restlessness, laughter or crying tween one and three hours afterwards he was inter- wed again and his anxiety was judged he was en asked to define medical terms used at the bedside e patients were adults except for 4 girls between e ages of nine and twelve and 1 boy of thirteen eir ailments included infections deficiency diseases, etabolic disorders, neoplasms, degenerations and ychogenic illnesses The preliminary examination owed that 29 men and 30 women had little 9 men nd 16 women much anxiety associated with their lnesses; in 2 women the illness was predominantly eurotic and there was confusion or a variable egree of awareness in 11 men and 3 women

[1] *J Amer med Ass* Aug 30, 1941, p 664

The demonstration produced no severe emotional rauma in any of the patients Nearly all were grate- ul for the preliminary explanation There was, of course some anticipatory anxiety which reached its peak when the group entered the ward and came to the bed and then subsided, 24 patients including both the neurotics admitted to feeling uneasy and tense, 12 of these belonged to the group of 25 who were already anxious about their illness, and 7 to the group of 14 who were confused Only the two neurotics showed significant changes in pulse and blood-pressure Repetition of the history distressed 13, especially when this was the occasion for learning unfamiliar facts One youth discovered for the first time that he had had fits during the course of his illness and was greatly disturbed, a woman disliked a reference to a previous attempt at suicide, a man was wounded by the description of his ill-fitting shoes as "second-hand" The physical examination only annoyed 7 Some were embarrassed by being made to undress before an audience and others were troubled because attention became focused on aspects of the disease which—to them—had previously seemed trivial Thus a boy with diabetes and nephrosis became anxious when his heart was scrupulously examined "I haven't got heart disease, too, have I?" he asked Group laughter worried nobody, usually the patients could share the joke and joined in Of 69 patients who remained for discussion of their cases 11 would rather have been removed, most of them because they felt tired or hungry or were in pain Of 31 patients who were removed 16 would have preferred to remain, so that on the whole curiosity outweighed discomfort Divergent opinions in the group seem only to have impressed patients with the thoroughness with which cases were being studied, which belies the oft-told story of a patient who, having listened to the unanimous opinion of a group of dressers that his tumour was benign and the honorary's "I propose to operate at once" got out of bed and went home, remarking "No, you don't!"

Definitions of medical terms by patients showed how wide interpretation may be of the mark Neoplasm, mitosis, metaplasia and metastasis fortunately had no meaning for any patient Shock, stroke, and paralysis were used interchangeably Neurotic was defined as "nuts" or "due to imagination," but "nervous breakdown" was accepted as a respectable consequence of overwork Degenerative was interpreted as implying moral decay, and "prognosis" meant "no hope" for some This section of the investigation has a special interest reminding us how constantly we should be on guard against the use of terms which may spread not only alarm and despondency but undue hope Thus it is common experience that for most patients the word "progressive" means a disease which will get progressively better, that "Graves's disease" carries the most gloomy interpretation; and that many a mother has been convinced that she must face a breech delivery from the use of the term "occipito-posterior" On the whole, however, Dr ROMANO has shown that though patients may grumble a bit they are not unduly upset by ward rounds, and that a little extra care and vigilance will serve to allay what anxiety such experiences produce

Annotations

FEEDING THE MINER

SINCE attention was last drawn in these columns to the need for supplementing the rations of workers engaged in heavy industries such as coal-mining steps have been taken to make supplementary rations available to miners The Ministry of Food has been anxious to secure that this supplementary food is in fact consumed by the miners themselves and it has therefore been considered necessary to make the issue at the mines concerned There are several possible methods of making an issue of this kind—by the provision of packets of food containing pies meat patties &c which can be given to the miner at the pithead for consumption either underground or when he goes home by the provision of hot meals at the surface on completion of the working shift or by sending suitable hot food down to be consumed underground during the mid-shift break Each of the first two methods has been adopted fairly widely with what success it is not yet possible to say. The first can at best provide a better cold "piece" which is obviously not ideal, and it may well be easiest to provide a hot meal in a surface canteen at the collieries that have already been equipped with pithead baths through the activity of the Miners Welfare Commission Mr David Robertson MP, favours the third method—a hot meal underground in the middle of the miner's working spell The difficulties of this must vary a great deal from colliery to colliery but it should not be impossible to serve hot meals under these conditions at several points for comparatively small groups of men Many hospitals use thermos-like containers capable of carrying ample food for twenty or thirty patients and keeping it at constant heat for a time amply sufficient to meet mining circumstances It may be that any system of distributing food underground raises difficulties in relation to payment and so on, and that the only practicable solution may lie in sending down individual containers with one man's ration in each Even that should not be impossible with a little ingenuity on the part of the makers of containers Experiments have been carried out at a Midlothian colliery which promise good results in this distribution of hot food underground and the men in that colliery are said to favour the method Mr Robertson lately demonstrated some containers to members of the House of Commons and it seems probable that this system will be tried out on a more extended scale It will be interesting to see whether developments along these lines do anything to remedy the notoriously high incidence of gastritis among coalminers Efforts of this sort can scarcely fail to improve the miner's lot and must in the long run contribute to efficiency and output

TRANSPORT OF CARBON DIOXIDE

MOST of the carbon dioxide carried from the tissues to the lungs is in the form of bicarbonate in the blood plasma The limiting factor of the rate of CO_2 absorption in the veins and evolution in the lung capillaries is the stage $CO_2 + H_2O \rightleftharpoons H_2CO_3$, because this reaction, being molecular and not ionic, proceeds comparatively slowly, so slowly that if it were unassisted only 1% of the CO_2 known to be given off in the lungs from the blood could be given off in the second or so that the blood takes to pass through the lung capillaries The assistant is the enzyme "carbonic anhydrase" which catalyses the reaction so that it proceeds at a proper rate Oddly enough carbonic anhydrase is chiefly found not in the plasma but in the red blood-cells, so that evolution of the CO_2 in the lungs involves a complicated series of reactions

The CO_2 is derived from H_2CO_3, carbonic anhydrase assisting the reaction, within the red cells , the H_2CO_3 comes from the potassium bicarbonate in the cells, which reacts with hæmoglobin, $KHCO_3 + H\ Hb \rightarrow K\ Hb + H_2CO_3$, the potassium bicarbonate of the cells is derived from sodium bicarbonate of the plasma by the exchange of Cl^- ions

$NaHCO_3 + Cl^- \rightarrow NaCl + (HCO_3)^-$ in the plasma
$(HCO_3)^- + KCl \rightarrow KHCO_3 + Cl^-$ in the cells

This interchange, familiar as the "chloride shift," occurs because the cell envelope is permeable to anions—Cl^-, $(HCO_3)^-$—but not to kations—Na^+, K^+ The net result is that CO_2 is given off and the plasma bicarbonate is reduced, and it is the activity of carbonic anhydrase that governs the final velocity of the reaction The original work on carbonic anhydrase involved the destruction of the red cells by laking because standard manometric and colorimetric methods could not detect the activity of the enzyme in the intact red cells Keilin and Mann,[1] by using a spectroscopic method, have now been able to show carbonic anhydrase at work within the intact red cell They utilised the fact that hæmoglobin can be oxidised to methæmoglobin while the red cells remain intact Methæmoglobin can act as an indicator since it changes its colour and its absorption spectrum when the acid form changes to the alkaline form between pH 6 5 and 9 5 Acid methæmoglobin can be changed to the alkaline form by adding carbonate or alkaline phosphate to a red-cell suspension or vice versa by adding CO_2 or acid phosphate By using a special spectroscopic microscope eyepiece and matching the spectrum of the reaction chamber with the spectrum obtained by illuminating a movable wedge-chamber containing standard solutions of acid and alkaline methæmoglobin, they were able to estimate the amount of acid or alkaline methæmoglobin formed at regular time intervals, and so obtain a graph showing the velocity of their formation When carbonate was added to a suspension of red cells containing acid methæmoglobin, 50% was changed to the alkaline form in 34 seconds From what is known about CO_2 transport and its relation to changing alkalinity of the plasma, it was expected that carbonic anhydrase was also the limiting factor in these test reactions Mann and Keilin[2] had previously shown that carbonic anhydrase is strongly inhibited by sulphanilamide, and this drug has the advantage of not reacting with methæmoglobin If therefore sulphanilamide inhibited the test reactions, confirmatory evidence that carbonic anhydrase was the active enzyme responsible would be provided This evidence was easily obtained, addition of sulphanilamide to the cell suspension greatly slowed the reaction , in a concentration of 5×10^{-4} M the 50% formation of alkaline from acid methæmoglobin took 210 seconds In a similar but more complicated experiment, still with intact red cells, Keilin and Mann were also able to show that the actions which induce the chloride shift are also d by sulphanilamide and are dependent on the acti carbonic anhydrase

We might thus expect that in anæmia, and also in sulphanilamide poisoning, insufficiency or tion of carbonic anhydrase would lead to disturbance CO_2 transport and also of oxygen transport since the closely interact There are two reasons why does not happen First, there is a large reserve of bonic anhydrase, estimated by Lambie[3] as equal to times normal physiological requirements He fo that the anhydrase content of the blood could be redu to a fifth of the normal without any signs of CO_2 re tion appearing The second fact is that there exists alternative method of CO_2 transport which does require acceleration by an enzyme or catalyst carbonic anhydrase is put right out of action the bl still takes up about 20% of the possible CO_2 instant eously, the rest being taken up gradually as expecte Roughton[4] showed this was due to the formation of carbamino hæmoglobin compound according to reaction

$$Hb\ NH_2 + CO_2 \rightleftharpoons Hb\ NH\ COOH$$

This alternative is actually more important than is first obvious because reduced hæmoglobin has be found to form this carbamino compound more readi than oxyhæmoglobin, so that Roughton estimates th 75% of the extra CO_2 taken up at constant CO_2 pre when hæmoglobin is reduced is due to this reaction a only 25% is carried as bicarbonate Thus thorough does nature provide for the protection of the vital C elimination and oxygen absorption under the mo adverse circumstances

VENEREAL DISEASE AND HOME VISITING

THE inoculation of a sensitive social conscience in those who lack one is the aim of many workers in t field of social service From time to time efforts ha been made to visit defaulters from venereal disea clinics in their homes and a recent successful experime of this kind was reported by Dr J L Burn in ou columns[5] A health visitor who acted as part time nur in the venereal disease clinic undertook the hom interviews and confined her visits to defaulting wome and children She succeeded in getting more th a third of the 134 defaulters to attend regularly an another eighth to attend irregularly There are dif culties in the way of extensive home visiting, howeve though they are not necessarily insuperable At small clinic, where the consultant only attends on give days, it is relatively easy to arrange for the social work to do her visiting in the intervals of his attendances, b in a larger clinic, where consultants are working dail it is difficult to arrange for the social worker to be absen And now that many more women patients are at wor much of the visiting must in any case be done aft clinic hours In small areas the V D social worker also the health visitor for the antenatal and maternit and child-welfare departments This was so in the are described by Dr Burn, and the arrangement had th advantage that the patients and their neighbours kne her and did not identify her merely with the venerea disease clinic In larger areas it is unlikely that a soci worker could undertake such a combination of duti and the visiting would have to be done by an almon or nurse connected only with the clinic , the drawbac here is that the patient's neighbours might recognis the visitor and draw their own conclusions Expectan mothers are probably the easiest group to visit wit success, since they are often at home and probabl alone, except for any other children, during the greate of the day The anonymity of the visitor will n much to patients, and methods of maintaining hould be well considered Where children are ring from congenital syphilis or have acquired ovaginitis it is rare for parents to refuse treatment them , when they do the N S P C C is willing and petent to deal with the situation This voluntary y will also help when an infected mother refuses tment for herself or wishes to have her child who has n cured of vulvovaginitis back at home with her large hospitals visiting may be difficult because the hering ground is so great, and if many names and resses turn out to be fictitious it may be deemed to te too much time There is evidence, however, that ple are not giving false names and addresses so freely vadays , and the provision of a little car for the itor—anyhow in peace-time—should overcome diffities of range No doubt the personality of the doctor n by the patient at the first attendance and the truction then given verbally and by leaflet on the ture of the disease are important in keeping the faulters rate low At the Lock Hospital much iance is placed on this first interview, and letters only e sent out to recall defaulters Only a very small rcentage finally default under this system, and it must remembered that some patients only come to a spital to get an expert second opinion , when their spicions are confirmed they return for treatment to e private doctor or the medical officer at the local inic who first made the diagnosis Yet no system can e regarded as perfect which allows even a few infected eople to escape the net of treatment and spread the isease among their fellows

IN DEFENCE OF A SEA DOG

WHAT distinguishes a pirate from an honest man ? hiefly, it seems, the lack of a licence to practise , but this is a distinction which ought to appeal to the medical profession Drake was a pirate until Queen Elizabeth made him a captain in her Navy , after which he went on doing exactly what he had been doing before—but how much more respectably Thomas Dover, whose memory Prof J A Nixon tells us (p 774) we have been slandering, was never a pirate at all He was a member of a privateering expedition against Queen Anne's enemies in the South Seas As we were then engaged in the war of the Spanish Succession, it is a pleasure to record that Dover's share in the sacking of the city of Guayaquil in Peru, and the taking of a Spanish prize, come under the heading of strict attention to duty He was captain of the *Duke*, and later of the prize ship, but his colleagues, feeling no doubt that navigation was always a difficult art, would not let him sail them They gave the responsibility to Alexander Selkirk, picked up from Juan Fernandez where he had been waiting for a lift for over four years and unconsciously providing the scenario for "Robinson Crusoe" After sacking the Peruvian city the English sailors slept in churches where they were much annoyed by the smell of the recently buried corpses of victims of a plague epidemic ; and forty-eight hours afterwards, when aboard again, they all fell sick On this occasion Dr Dover can be exonerated less confidently from a suspicion of piracy, anyhow in a professional sense , he held no medical charge as Professor Nixon reminds us, but he took over conduct of the epidemic, directing the official surgeons to bleed the patients in both arms to the tune of 100 oz apiece After that he gave them dilute sulphuric acid to drink, and they all recovered except eight—no mean achievement on their part since the malady proved to be true plague Dover, however, was never afflicted with the miserable virtue of moderation He was a natural partisan of remedies, especially of metallic mercury which earned for him the name of the Quicksilver Doctor Pirate or not—and we must of course agree with Professor Nixon and Sir William Osler that he was *not*—he was a fine full-blooded figure to have in our medical annals, from whom we, as his anæmic posterity, might welcome a transfusion Such an enthusiast for phlebotomy should make an ungrudging donor

PNEUMONIA TREATED AT HOME

THE value of chemotherapy in pneumonia is well authenticated from the records of patients treated in hospital where diagnosis can be readily confirmed by X ray and pneumococcus typing, and where treatment can be controlled by laboratory tests and the patient's progress continuously watched The proportion of pneumonias treated in hospital varies greatly in different areas, but the ease of administration of the sulphonamides and the ready response of the patient to these drugs will doubtless lead to a greater number of cases being treated at home It is therefore important that the home treatment of pneumonia should be both efficient and safe , in other words, that it should destroy the invading parasite without damaging the host Some physicians are too heroic with this new weapon, forgetting that the sulphonamides are toxic substances, and unfortunate accidents occur—anuria from too high a concentration of the drug and insufficient fluid intake, or granulopenia from too persistent treatment. Others are over-cautious with the size of dose or stop treatment too soon so that the infection either smoulders on, perhaps with a pneumococcus now rendered drug-fast, or relapses after apparent cure Treatment, with either sulphapyridine or sulphathiazole (the latter if available is as effective as sulphapyridine and less upsetting to the stomach), should aim at moderation American workers[1] have found that there is no difference in the response of a pneumonic infection to blood-concentrations between 2 and 15 mg per 100 c cm of these two sulphonamides, and they regard a total dosage of 25–30 g as sufficient to control most pneumonias The initial dose should be 2 g (4 tablets) of sulphapyridine or 3 g of sulphathiazole, followed by 1 g every four hours for the first two days, and 1 g every six hours for the next three days With sulphathiazole particularly it is advisable to continue the four-hourly dosage day and night, for this drug is quickly excreted and therefore a steady blood level is less easy to maintain Here, sulphadiazine has a distinct advantage, for an effective blood-concentration of it can be maintained with smaller and less frequent doses

Pneumococcus typing has never been popular in this country, and the new chemotherapy has pretty near sounded its death-knell Yet pneumococcus typing not only gives valuable help in diagnosis—the isolation of a type I or II pneumococcus in an ill patient is practically diagnostic of lobar pneumonia and in most urban areas over half the lobar pneumonias are due to these two types —but it also helps considerably in prognosis and gives useful epidemiological data That it can be carried out and prove informative in domiciliary practice has lately been demonstrated by McClure,[2] working in the central laboratory of the Provincial Department of Health of Ontario in close association with practitioners in the surrounding districts Pneumococcus typing for the practitioners had been done in this laboratory since 1934, and of 1000 questionnaires sent out for information about the typed cases 647 were returned In 495 cases pneumonia was present, and some form of chemotherapy, usually sulphapyridine, had been given to 386 of these There were 21 deaths but in 2 of the fatal cases sulphanilamide had been given and in 6 others death was due to some other condition after the pneumonia had resolved Excluding these 8 cases the fatality was 3 7% which may be compared with a rate of 9 5% in an earlier and similar series of 306 untreated cases , 80% of the deaths in the latter group, but only 30% in the drug treated series, were under 60 years of age The average amount of drug given was 18 4 g per case, and McClure notes that not only was there a tendency to give too little drug but also to stop the drug too soon As for the distribution of pneumococcus types in this series, it is noteworthy that only 83 out of 386 (21 5%) belonged to types I and II, a striking difference from the usual distribution in towns Similar investigations could be organised in this country and would probably yield much interesting information

INTRAMUSCULAR BLOOD IN CŒLIAC DISEASE

Arguing that some disturbance of the internal secretions is the cause of cœliac disease, J Wickstrom[1] of Helsingfors advocates its treatment by intramuscular injections of whole blood The blood, from healthy adults, usually relatives of the patient, was injected into the gluteal region in doses of 15–20 c cm without any additions at intervals of 2–5 days for a series of 10–30 injections During this treatment all other measures were suspended An average mixed diet, suitable for the child's age, was given with generous milk and milk mixtures, porridge and so forth—in fact a diet which would usually be considered quite unsuitable for patients with cœliac disease Several cases were treated at training hospitals for nurses with frequent changes of staff so that the good results obtained cannot be attributed to expert nursing care Five children with different combinations of symptoms, but all undoubtedly examples of cœliac disease, were treated No sudden change in symptoms occurred and to begin with the stools remained unchanged But after a few injections the weight began to rise and this improvement continued steadily throughout the course of injections with a corresponding bettering of the appetite After 2–3 months the weight had risen by between 1 and 4 kg and the whole picture of the child had changed The extra weight gave the limbs a better-proportioned appearance, the abdomen became less distended, muscle tone improved and the child's general behaviour, including temper, showed a striking change for the better The stools tended to remain of the cœliac type for some time when normal stools began to appear, often alternating with cœliac stools The blood sugar curves, however, retained their low characteristics and a tendency to low blood-phosphorus was also unchanged It is not claimed, therefore, that cœliac disease is cured by whole blood injections, but it seems clear that the general condition is so much improved that other treatment is unnecessary Wickstrom urges that this form of treatment is indicated when the general state of the child with cœliac disease is bad, with much wasting and loss of appetite In fact it is during the worst phases of the disease that good results can be obtained by whole blood, and thus a big step towards final cure can be taken just when other therapeutic measures have failed It might equally be argued that it is just at such a stage that a dramatic turn for the better often takes place without any special method of treatment, so that Wickstrom's modest claims will have to be confirmed

INCREASE OF SCABIES

Using as his material the patients admitted to infectious diseases hospitals in five English cities during the past ten years, Kenneth Mellanby[2] deduces that the incidence of scabies from 1931 to 1937 was low and regular in distribution but in 1938 began to rise briskly and since that year the rise has accelerated Roughly, before 1938 the incidence in fever patients was 3 per 1000, whereas by 1941 it had risen to 25 per 1000 The incidence varied in the five hospitals but the upward trend was the same in all The rise started before the war, and though war conditions have probably helped the spread of the disease they cannot be proved to have done so In one of the cities there had been evacuation, in another there had been little, and life" was common in two but absent in a third scabies graphs are nearly similar for all three cause of this rising epidemic of scabies is Mellanby suggests that the increase in dancing cinema-going between 1930 and the outbreak of be in part responsible for it Some will not accep thesis that the incidence of scabies in the general po tion is similar to that in patients admitted to hospitals, but there can be little doubt that the will be much the same Attention was called to increase in scabies by many school medical office their 1938 reports, so the beginning of the can be dated

THORACIC SURGERY AT LEEDS

Mr P R Allison has taken over the direction department of thoracic surgery at Leeds Genera firmary, relinquishing his appointment as hon surgeon This teaching department is breaking ground, the London Hospital and the General Hospital have such units, and there are tho surgeons at many large hospitals, but Leeds clai have the first thoracic department to be opened provincial teaching hospital At present there 10 surgical beds—5 for women and 5 for men—res for thoracic cases, which will form a war time nuc later, when the hospital has its normal complemen beds, it is hoped to have more Mr Allison, to w energy and foresight the department is largely due, be assisted by an anæsthetist and a resident surgical of

SIDEROCYTES IN MAN

Not long ago Grüneberg[1] found that granul "free" iron could be detected by the prussian test in the red blood cells of mice suffering fro inherited disease typified by "flexed tail and spot" A few such cells also appeared in embryo newly born normal mice and rats, and Grüne thought that they might also be found in man, if were looked for He now reports[2] that small perc ages of siderocytes have been found in the bloo human fœtuses, the figures varied from 0 10 to 4 and the amount of siderotic material was usually s Gruneberg has tried to link up the presence of sideroc with the change from megaloblastic to normobl erythropoiesis, this is unlikely since in man the ch takes place at an early stage, being complete at the 8th week whereas the age of the fœtuses w blood was examined for siderocytes ranged from 3 40 weeks The significance of the siderocytes is known, present theory points to iron being transp in the plasma and combined with hæmoglobin in bone marrow, nor does it normally become "f again until the hæmoglobin is liberated by the br down of the red cell Their presence in normal emb favours the suggestion that the free iron represen hitherto unknown mode of hæmoglobin synthesis ra than a disturbed hæmoglobin metabolism

Sir **Alfred Webb-Johnson**, P R C S, has elected a vice-president of the Middlesex Hosp This is we believe the first time this honour has conferred on a member of the active staff

Dr **R Dawson Rudolf**, emeritus professor of th peutics in the University of Toronto, died on No after a short illness He was a graduate of Edinb University and was elected to the fellowship of Royal College of Physicians of London in 1910 renewed old associations on the European battle in 1917–18, taking special interest in trench fever, his popular little book on the Medical Treatmen Disease had the critical outlook which marks scientific observer

In England Now

unning Commentary by Peripatetic Correspondents

or some of us it is hard not to feel sentimental about tately-homes-of-England-how-beautiful-they-stand, we must reluctantly face the fact that they are al- y anachronisms, lovely vestiges of a more leisured If it seems unlikely that any more of them will e in our time it is consoling to reflect that many of e still standing, their owners gone or roughly herded a couple of unwanted attics are proving useful for sing evacuated communities of one sort or another ne of them are making excellent hospitals convalesc- homes or school buildings even if the spectacle of ith minor carving his initials on the old oak in the ing-hall causes their former masters to revolve steadily in the family vault But the smaller places taining let us say, a mere score of rooms have not n accustomed to harbouring a population of more an 20 all told (including the indoor staff) and when ed to accommodate perhaps two and a half times that mber are apt to show their resentment in various ys If the old squire his family and retainers could ike do well enough with three bathrooms and the same mber of water-closets the new school needs twice as any The fact that these are constructed as fast as revailing conditions permit does not solve the problem, r at this point the wells run dry, and the new bath- oms, to the eye imposing as they are, yield but few d scanty baths and in dry weather go on strike alto- ther, calling on the water-closets to follow suit To be ashed with success may be for you or me just a pleasant xperience, for a water-closet it is imperative More ells have to be sunk, pumps and storage tanks installed before the old house is satisfied

* * *

Our examination system is very fair, particularly in ssociating a newly appointed junior with a senior of xperience to calibrate his sense of values and teach him hat he must not be too exigent He learns in time that a candidate may be an excellent practitioner in embryo lthough he has the most feeble capacity to describe and xhibits a contempt for good English which is not the contempt bred of familiarity A favourable impression s hardly created by the statement of a candidate that he patient is usually a male or a female, that such and uch should be suspected until found absent, that the mportance of this symptom is very important, that sleep should be attended to, that a fat person may cause confusion (apparently the intention was to inform the examiner that adiposity handicaps diagnosis), that the occurrence is unfortunate but of no significance For such as these we have pity, but it is not the pity that is akin to love

We soon abandon any expectation of encountering even the most elementary approach to style and construction we accept the pabulum as containing all the necessary elements for our nutrition and do not trouble about the way it is cooked and served Later we lose our wonder at the evidence of extreme illiteracy I have collected the following from the paper of *one* candidate (I am telling the truth, although I am certain that nobody will believe me) I omit the errors which are practically universal such as preceed, accomodate, occurence, apetite and others of that type, and confine myself to technical terms Flem, Sharco joint, scabalæ, Pix disease, ematiated, caxecia, paracytic syphillus, sight (site), stimulous, physic (physique), tacicardia, inflamertory, annorhexia, naushia, tabbacco, tick (tic), spescial, redenned, tosis, fibrilattion, ocluds (occludes) Now here is a queer thing This candidate scored well over 60% in his paper and I am puzzled to explain his illiteracy The obvious explanation is that his knowledge was acquired exclusively or mainly through his auditory channel and that he had never familiarised himself with the appearance of the words Yet this plausible explanation is not satisfactory since the character of his answers supplied evidence of fairly extensive reading One is inclined to suppose that spelling must be a special ability which comes to some people independently of phonetics or the extent of reading

Not only may the paper be unreadable, it may be illegible I sometimes marvel at my own patience when plodding wearily through almost completely undecipherable scrawl and even tolerating such carelessness as pinning pages out of order In fact I am inclined to believe that illegibility may, like stammering, be a distinct advantage The conscientious examiner, remembering that there may be much fertile matter in a muddy stream and unwilling to court a possible injustice may prefer to presume the existence of something which might be identified through more trouble on his part He would rather be a good-natured fool than conscience-stricken, remain self-convicted of caddishness in penalising a physical defect or an attribute albeit premature, traditionally regarded as a doctor's perquisite

There appears to be some difference of opinion among the experts as to the best procedure to ensure the highest possible degree of professional efficiency and general culture as a writer in the *Lancet* put it a few weeks ago in advancing his "plea for graduation at an earlier age" He deprecated the smattering of Greek and Latin and preferred the arrangements whereby clever boys of 16 already possessing a good grounding in biology are plunged in medias res Yet actually on the same day I was confronted with a letter to the *Times* from the headmaster of a famous public school approbating my illustrious friend Professor Ryle and condemning early specialisation (I was sorry to see his reference to the Regius Professor of "Physics" at Cambridge University but I am sure that this must have been a playful printer's variant and not a lapsus calami) Other things, he reminds us, are expected of a doctor than technical knowledge—he is notably a man of science; he is a citizen holding a most responsible position in society, and as such his education should equip him with wide interests. In support comes a letter from a Scottish professor of anatomy whom we recall with affection when once upon a time he instructed our London youth until the call of his native town proved too strong against even our blandishments He says that on returning to his own university he was relieved to find an absence of that degree of sheer illiteracy to which he had become painfully accustomed in examination papers in the south This he attributed not to any inherent superiority in modern Scottish school education but to the proper proportion of the cultural subjects Is it too late, he asks, to plead for the restoration of Latin as a compulsory entrance subject? An elementary knowledge of Latin or Greek is he thinks surely essential to the study of a profession whose terminology is almost entirely founded on those languages He instanced the student who duly impressed by the derivation of the omo-hyoid muscle inquired "Well what about 'omo sapiens"? The story he assures us is painfully true and recalling the examination papers I have recently corrected I have no difficulty in believing it

* * *

It is good for the soul from time to time to re-examine principles, and try to find out how much foundation they have in fact One may be led to strange conclusions It has long been assumed that the bigger chubbier and heavier the baby the better it is that the child should be large and firm with a "good" colour and good teeth, in fact the standard nutrition should be "A" *in terms* of the school medical examinations This phrase nutrition A is vague Nearly all the experiments done to demonstrate the desirability of this state of health have used children or young animals and the rate of growth has been one of the main criteria There is indeed some evidence that with the improved diet which many children get there has been an increase in average size (post or propter?)

If we ask the obstetrician whether a hard, large and well-calcified infant, or a small relatively rubbery infant makes the passage through the birth canal more easily we are told that the latter has an easier voyage Does any mammal increase its food intake or drink the milk of other lactating animals during pregnancy? Is it not possibly an advantage to have a low blood-calcium near term, so that the uterus may be more sensitive to the stimulus to contract? Immediately after recovery from labour I imagine that most mammals increase their food intake, and so should women Let them take their lime and phosphates their ergosterol and carotene derivatives and their metallic salts in the puerperium, both as an aid to lactation and in anticipation of their next pregnancy

The strictest physical examination in Britain is probably that of prospective pilots in the Royal Air Force I don't know what the average height and weight of these men is but they seem to be below the average of the population both in stature and girth, yet they are physically one of the soundest groups of men in the world Again, complete life tables show that age for age men of slightly less than average height and weight have a better expectation of life than men of greater stature and bulk So is nutrition A really for the best? We might do better to produce a race of small wiry individuals

* * *

The most beautiful thing in my garden at the present moment to me at any rate, is the notched green leaf of *Barbarea præcox*, a winter cress which is going to provide me with salad for the next few months It is, I am told named after the holy Barbara of Nicomedia, patron saint of gunners, who has her day on December 4 The summer flowers flaunt their fading beauty, the chrysanths like hardy courtesans beckon me with waving grace and dye and subtle smell, I scorn the lot With sense and season I seek more solid pleasures The feeling of beauty in man (pace Professor Joad) is entirely utilitarian in origin and in younger communities is demonstrably so now It was only with the coming of the unnatural leisured class unheld by primary needs, that it became elaborated Colour that was meant to tell of ripeness became a creed, productive country a landscape, the beauty of woman and child, a lure to breeding, became in form and contour a fetish Then this feeling was in many cases seized and refined by that strange phenomenon which I term "exclusive grouping" This you see best in the small boy whose gang has a secret sign, an adult form is Freemasonry You see it in dress—that fellow who wears a made-up tie is beyond the limits of loathing But above all you see it in the arts—he who cannot appreciate (as we do) the music of Bong is surely bestial, or the painting of Cong is a class outsider, or the verse of Dong is a tick of the outer edge Probably protective

As a change from a life made up of sewers forms and the horrors of the state let loose in medicine, I have become an amateur veterinary surgeon Now I am seeing as many furry patients as their human counterparts, and it is strange how akin they are Diana, a sleek lady spaniel in black satin, is as perpetually feminised as a certain sophisticated patient of peace-time practice As soon as a male of her species enters, Diana exerts all the usual tricks of her sex, although her languorous eyes are sadly handicapped by a streaming conjunctivitis Her human counterpart could also spare a glance of interest and appreciation even when in the most excruciating agony Both had, of course, "seen many other doctors before I came to you, doctor" There the resemblance ends, for Diana's eyes cleared up at a surprising pace and she is glamorous again The rapid onset and equally rapid cure among the animals surprises me Porky, a spunky sealyham, was brought with a large corneal ulcer and corneal vascularisation In other spheres I should have given a gloomy prognosis, but from a dull, torpid, butting-into-chairs quadruped, he was back to cat chasing and all other normal activities in two weeks I nearly said "fit for parades, P T, parashot, guards, and games," but the Service has not caught me as much as that—yet A host of minor points crop up which puzzle me in this new vocation How much sulphapyridine should be given to a flock of hens suffering from coccidiosis and when and how should it be given? The vet said "Burn 'em all" but the large flock is surprisingly still in being after change of ground and thorough cleaning of the pens I hope to succeed in this hen racket, as most traditional hen cures seem to go back to the tar-water and boiled-beetle era Various fractures have also appeared, but my ambition to treat a bilateral fractured femur of the hind legs (how do the vets describe this?) in a dachshund by a roller skate strapped under the tummy did not meet with the approval either of the dog or the owner A haughty spaniel scorned to use my plaster with walking iron applied to his fractured femur (off fore), now I know which fractures need plaster and which do better by natural methods Another pitfall turned up when a little terrier pup was treated for worms on evidence which was later found to be an elastic band one of many swallowed in a successful raid on the stationery The cure of some pets has baffled me, including pekinese, who seems to say a doctor's family is badly treated I believe a large beer bottle filled hot water between the legs is helpful, although it him into a caricature of an incorrigible toper a last pint in bed After all this I must write a dum on pets The home treatment is confused wifish and needs drastic overhaul I can see no why what works in the rest of the family should not in them (if we can get the doses right)

SURPLUS OF IRISH DOCTORS

THE Eire papers have been discussing whether are too many doctors in Ireland It seems that knows how many there are at present or how many were in more normal times Neither the M Register nor the Medical Directory gives much many medical men practising outside of Ireland the habit of giving their home addresses for years they have left the country, probably because the home is their only permanent address A few years it was calculated that though there were between and 3000 practitioners in the Medical Register wi Irish addresses, the number in actual practice in Eir itself was not more than 1500 The number now, including those in practice and those unemployed, i probably much greater than this The reasons for the increase are not far to seek For generations the Irish schools have educated large numbers of medical men for export The output was far greater than the home demand Young Irish graduates went to make their living in England and the British Dominions where the Scottish graduates they were well received and were usually reasonably successful This outflow is much diminished since the war began It has not been eas to obtain a permit to cross the Irish Sea, though th authorities do not, as a rule, refuse permits to tho who have obtained posts in Great Britain The usually refuse permits, however to those who merel wish to seek employment In the past many youn Irish doctors took resident posts in the British provinci hospitals, after attending a preliminary interview they are now unable to obtain travel permits in order t attend such interviews, and so a high proportion o recent medical graduates are compelled to remain i the land of their birth Moreover a considerab number of young Irish medical men who were worki in England have returned home crowding further a already overcrowded market No doubt some of the had always intended to return to Ireland when they ha gained some experience in England

Lay and professional correspondents in the Irish pre have pointed out that the present supply of medic men is greater than the present demand, but few see to have asked whether it is greater than the present nee They have been more concerned with the livelihood those in the profession than with the needs of the countr Many of the essential public services are, in fact, mu undermanned This applies especially to the coun hospital service and public-health services Most of t county hospitals are new and well constructed but qu inadequately staffed The personnel usually includ a single surgeon, who is a whole-time officer except f consulting work, an anæsthetist, and in some cases visiting physician The surgeon must also fill the rôles gynæcologist radiologist and pathologist No speciali help is provided except for the occasional visits of a ophthalmologist in some cases However able t surgeons may be—and they are good all-round surgeo —they have no opportunity of doing first-class work

In the local health services a county medical offic of health and a county tuberculosis officer are to be fou in each county The county M O H has to be scho medical officer in addition, this school work has be undertaken with great zeal, but in few counties has t M O H had time to examine each child more than on during its school life Without more assistance t service—which should be one of the most repaying—mu continue to fall short of what is possible The poor-la dispensary service is probably adequately staffed in t ntry districts, but is grossly undermanned in the es , much of its work is undertaken by the outpatient artments of the voluntary hospitals, which are reby diverted from their proper task of providing sultant services The country needs an increase of personnel of the public services by at least half as ich again, but at the moment the central and local thorities are unable or unwilling to provide the quired funds Yet until the public services are veloped there should be no talk of too many doctors

Some medical teachers maintain that teaching is mpered by the large numbers[1] in the classes, and ecially in the clinical classes This difficulty, if d where it exists, seems to arise from faulty organisa- n of the clinical teaching, which in the Dublin hospitals done by seniors, who, as examiners, naturally attract large number of students If they shared more of eir work with their juniors, the size of classes would come more manageable

It would be hard to break the tradition of the Irish hools in educating more doctors than the country can ovide work for, even if it were wise to do so Many ink that the country gains prestige from the quality f the doctors who leave it to work in other lands Were he schools to limit drastically the number of students, any would still choose the wider field for their future areers and Eire would be inadequately supplied But rish emigrants—whether professional men or manual abourers—are not a complete loss to their country Many of them send home help to their parents and elations which more than repays them for the expense of heir education

THE FORTIFICATION OF FOOD

On Dec 3, in the rooms of the Chemical Society at Burlington House, a successful joint meeting of two societies was held to hear papers on the Fortification (Enrichment) of Human Foods by the Addition of Specific Nutrients The chair was taken in the morning by Mr E B **ANDERSON**, chairman of the Food Group of the Society of Chemical Industry, and in the afternoon by Mr E B **HUGHES**, D Sc , president of the Society of Public Analysts Mr A L **BACHARACH**, F I C , who discussed the principles of food fortification, said he used the terms " fortification " and " enrichment " synonymously, although Mr D W Kent-Jones, F I C , and Mr A J Amos, F I C , who read the second paper on the technology of fortification, suggested applying " fortification " to procedures adopted to increase the amount of a nutrient present in a processed or manufactured food to the level present before such treatments, and " enrichment " to the addition of further nutrients over and above those normally present in the untreated food After considering the standard examples of food fortification—the iodisation of table-salt, the addition of vitamins A and D to margarine, and the Government's proposals for fortifying white bread (from 75% extraction of flour) with aneurin and calcium carbonate—Mr Bacharach put forward some general principles which should govern the fortification of all foods He insisted that there was no difference between " natural " and synthetic vitamins, that the object of food fortification was, in general, not restorative, that is to say, was not made primarily to restore to a food something taken from it by refining process, and further, that no heed should be given to the arguments that a particular addition to a food was undesirable because the added nutrient was not " natural " to a food Rather, he argued, fortification must be considered solely in relation to the proven need of a particular population for a given nutrient, and to the suitability of the food to which it was proposed to add the nutrient as a fortifying agent Questions of stability, price and palatability must all be taken into account All the resources of organic chemistry and chemical engineering, as expressed in the manufacture on a large scale of essential nutrients, should be mobilised to make good such specific dietary deficiencies as could be prevented by substances whose commercial production could be economically undertaken

Dr **KENT-JONES** and Dr **AMOS** summarised the methods adopted during the " vitaminisation " of margarine, in which thorough blending, with avoidance of aeration and critical choice of suitable fats and the application of rapid but adequate control tests at every stage in manufacture were all necessary to give a satisfactory final product They gave details of the fortification of bread with vitamin B_1 by the mechanical introduction into the flour stream of a specially prepared flour concentrate, the nature of white flour and crystalline aneurin being such as to make the direct admixture of one with the other impracticable They also referred to the irradiation of milk, or its fortification with vitamin D in other ways, as carried out fairly extensively in the United States, and to the incorporation of vitamin C in jams and preserves, a procedure not practised on foods to be sold in this country but carried out commercially on supplies intended for British prisoners of war They mentioned the difficulties that had arisen in the selection of a suitable type of calcium carbonate for the fortification of bread, but said that the creta præparata of the B P was satisfactory for this purpose

METHODS OF ANALYSIS AND CONTROL

After the lunch interval Mr H E **COX**, D Sc discussed the machinery for the enforcement of standards laid down for fortified foods. He thought that with the lapse of defence regulations, the Minister of Health would be found not to have the powers, at present held by the Minister of Food to enforce the positive fortification of food, but would return to the status quo ante bellum, under which he would at most be able to prohibit objectionable procedures and demand a maintenance of certain natural standards New legislation would be necessary if even voluntary fortification was to be permitted and adequately controlled At present, the addition of wholesome ingredients to foods was not forbidden by law unless this was specifically stated in particular statutes or regulations , it would be desirable for fortified foods to comply with certain legal stated requirements in which both minimum and maximum should be given for each permitted addition It was most undesirable to make regulations about the quality of food in general, and the nature and quantity of additions in particular, unless adequate analytical methods were available for those who had to help in the enforcement of such regulations Whether or not official methods of testing were desirable, recognised and standard methods would almost certainly be necessary, and in supplying these both the Food Group and the Society of Public Analysts should continue to play the valuable part they had played in the past. It was ultimately the public analyst's responsibility to secure that fortified foods, like any other foods, conformed with their descriptions on label and advertisement

The methods at present available for the estimation of minerals and vitamins in foods generally, and particularly in fortified foods, were surveyed in the last paper, on the analysis of fortified foods by Mr H E **MONK** After dividing the available methods into biological, microbiological and chemical or physico-chemical, and referring to the advantages and disadvantages of each, Mr Monk discussed the special methods devised for vitamin A vitamin B_1 (aneurin) riboflavin (sometimes incorrectly called vitamin B), nicotinic acid, ascorbic acid, and vitamins D (D_2 and D_3), showing that adequate chemical or physico-chemical methods were available for all of these, except for vitamins D_2 and D_3, for which a biological test is as a rule essential He also referred to the possibilities of a polagraphic method for estimating members of the " vitamin B_2 complex " and to the microbiological methods which are being developed in the United States much more extensively than in this country

	Dublin	Cork	Galway
First year students	352	79	57
All students	937	360	214

Letters to the Editor

SALT-WATER SURGEONS

SIR,—"Dover's powder, the nostrum of a pirate," you say in your issue of Nov. 8 (p. 568). This strange accusation against Thomas Dover, pupil and friend of Sydenham, seems to have been the invention of the late Sir William Osler. The expedition of the *Duke* and *Dutchess*, commanded by Captain Woodes-Rogers, on which Dover sailed was in no sense a piratical cruise. In 1708 some members of the Bristol Society of Merchant Venturers fitted out two ships which sailed to the South Seas. Captain Edward Cooke was second captain on the *Dutchess* and left a journal of the voyage which has been published. It is less well known than Woodes-Rogers' book and is the work of a better educated man. In it Cooke says that the commanders of the *Duke* and *Dutchess* had "commissions from his Royal Highness Prince George of Denmark, then Lord High Admiral of Great Britain, Ireland, etc." In other words the expedition sailed under letters of marque. They set out with four other ships, including the *Hastings*, *man-of-war* under Captain Paul. Commissions were granted to the two ships "to Cruise on the coasts of Peru and Mexico, in the South Seas, against her Majesties enemies the French and the Spaniards." Sir William Osler before his death frequently expressed his satisfaction that Dover was, as he put it, "such a respectable character," and fully retracted the charge of piracy. Dover's place in the expedition was that of representative of the owners, and in that capacity he was president of the council. He did not rank as one of the surgeons. These were, John Ballet who had sailed with Dampier previously, Samuel Hopkins, a nephew of Dr. Dover, James Wasse, surgeon, Charles May, his mate and John Lancy, assistant. Mention is made also of "John Vigor, a reformado, to act as Captain Dover's ensign when ashore." Yet Dover received £423 as *chief medical officer* in addition to his profits as a shareholder. Woodes-Rogers disliked Dover and complained of "want of sufficient medicines with which till now I thought we abounded, having a regular physician, an apothecary (i.e. Hopkins) and surgeons enough with all sorts of medicines on board." He would have preferred that Dover should have confined himself to the duties of a "regular physician." But this was not Dover's way. When a prize had been taken he claimed, successfully, to be appointed to command her. However the navigating officers felt no confidence in his seamanship and he was forbidden to interfere in any way with the navigation of the ship. It was agreed by a majority of the council (Dover presumably being in the chair) that "Capt. Robt. Fry and Capt. Will. Stretton, shall both act in equal Post in the Sole Navigating Sailing and Engaging, if Occasion should be, under Capt. Tho. Dover, on board the *Batchelor Frigate*"—thus the prize was newly named—"and that the said Capt. Tho. Dover, shall not molest, hinder or contradict them in their business, and we do appoint Alexander Silkirk master." The last-named was Selkirk whom the expedition had taken off the island of Juan Fernandez.

Dover's famous powder, compounded of ipecacuanha and opium, was not introduced by him as a narcotic. It was no "symbol of drowsiness and perspiration" to him. Dover regarded ipecacuanha as the active ingredient in his powder, a drug which was prescribed both as a febrifuge and as a remedy for dysentery. In fact it ranked almost with cinchona bark as a stand-by in the tropics. He added the opium to counteract the nauseating effects of ipecacuanha. Callander, in his "Voyages to the Terra Australis" (London 1768) speaks of this expedition as one of the best organised and equipped that ever left England.

The *London Magazine* for April, 1742, records the death of "Dr. Thomas Dover, famous for administering quicksilver to his patients, in the 85th year of his age. The last years of Dr. Dover's life were spent at Stanway House. He was buried at his own request in the vault belonging to the Tracy family." The statement in Munk's Roll of the College of Physicians that he died in London at his house in Arundel Street is wrong. The register of Stanway Church, in Gloucestershire, contains the entry that Thomas Dover, M.B., was buried there on April 20, 1742. The vault of the Tracy's is under altar, *but the church contains no memorial of the f* nor of Dover—an omission which it was Osler's have rectified, but the war of 1914 intervened.

Bristol. J. A.

CERTIFICATES FOR EXTRA MILK

SIR,—A good deal has been said in your columns about lax certification and multiple certificates but look like being put still more severely to the test with the distribution of extra milk and eggs. pressure will be put on us to sign certificates for c tions outside those for which we are entitled to do. These are very limited, but the indications are definite and leave no room for borderline lesions might be brought within them. Unfortunately t schedules have been issued in such a way that the will have the greatest difficulty in refusing a certif. No doubt before sending out the instructions the of the Ministry of Food thought it over carefully and good reasons for imposing secrecy on all co. They have come under "Confidential Cover—for *information of registered medical practitioners* only," with the added heading "Not to be Divulged to Public." How a doctor is to carry this out with a patient persistently demanding the certificate as a right remains to be seen. After having said ten times "No! your complaint does not come in the schedule of conditions qualifying for priority claims in liquid milk," he is almost bound to show the schedule in order to get the patient out of his consulting-room. We have to consider this in the light of the drink-more-milk campaign of recent years. Many a mother feels she has saved her weedy-looking son from consumption by making him drink a pint of milk a day. Many a shorthand typist who once had a lump in the neck thinks she will get "glands" unless she does the same. After supporting that campaign we cannot go telling them that it really does not matter. We can only say that the Ministry of Food has not got enough to go round, and that they must risk the invasions of the tubercle bacillus as they have the bombing plane. They will take it if they know, but the way in which it has been put forward makes it seem as though the doctors were capriciously depriving them of what they have a right to, and the medical profession was going back on these standards of preventive medicine that they have laboriously been building up of recent years. The reasons for the secrecy which balance these facts must indeed be weighty, and if the Ministry of Food can see their way to advertise the schedule in the daily papers and to post them on the doors of local food offices they will have a far better chance of their instructions being carried out. The people as a whole do not rush to obtain commodities to which they are not entitled and if they know that there is no extra milk for them thousands will refrain from asking their doctors for the certificate. We shall then be in a stronger position to resist the persistent demands of those who through fear or greed badger us for wrongful ones. Under the best conditions this resistance will not be easy.

Streatham. T. B. LAYTON.

POSITION OF THE BODY DURING SLEEP

SIR,—During my short period of clinical work I began to record from every medical case, and *indeed from* every available colleague or friend, the position he or she took up during sleep. It soon became clear that this was definitely characteristic for each individual. The individual seldom varied the position and when he did he was *fully conscious that he had made a change*. I often checked the statements of patients during night duty and found them to be correct, and I observed that the great majority maintained their position throughout the night. Two facts which are not unknown to physicians were often found: *that people with angina* pectoris avoid lying on the left side, and that patients suffering from acute and painful diseases occupy a position in which they feel the pain least. *A comparison of the position of the body during sleep in cases of true* angina pectoris and of heart neurosis might be worth following up.

I always asked specifically if there was any period in the lives of the subjects when they slept on their abdomen. Many people who did so for long periods were of either past or present liver or gall-bladder e Of 18 cases of catarrhal jaundice 15 had slept e abdomen from their youth up, or at least for years, whereas of 392 patients and healthy ols without any history of liver affection only 11 red this position A high proportion of patients cholelithiasis said they slept on the abdomen My amounted to only 400 and there were obviously too healthy controls on which to base a conclusion her research however, should show whether this vation in cases of liver affection can be confirmed, if so whether it is primary or secondary The minal position during sleep may be either the result he liver trouble or one of the factors which have ributed to it Some simple considerations seem to ate that the latter possibility can by no means be uded a priori The mechanical conditions under h the bile flows from the gall-bladder vary greatly the body position but there are other factors which play a more important rôle than gravity The a-abdominal pressure and its variations caused by iratory movements (of the diaphragm &c) may differ atly according to the position in which the subject is ig If he lies on the back the abdominal wall easily ves upwards when the diaphragm is lowered But en he lies on the abdomen the anterior abdominal wall omes much more rigid, so that inspiration should cause e intra abdominal pressure to rise much more To ese considerations may be added the effect the respira-ry variations in intra-abdominal pressure have on the culation of blood (and possibly lymph) in the liver e physiologist put it shortly by saying. "The liver pressed out like a sponge by the breathing move-ents.' These points show that it will not be easy to ecide whether the symptom is post hoc or propter hoc even one of the causes which predispose to an injury to e liver cell

These incomplete observations may perhaps encourage omeone who has the clinical material at hand to carry hem further and throw some light on a subject which eems to have been neglected hitherto

University of Birmingham. F SCHÜTZ

THE STICKINESS OF PLATELETS

SIR.—May I be allowed to make some remarks with regard to your annotation of Nov 15? In 1929 I published in collaboration with Miss Szekely the first functional test for blood platelets In these investigations the velocity of disappearance of platelets was determined in Kristensen's counting fluid This was called the velocity of platelet disintegration Mrs Payling Wright objects to that designation showing that many platelets disappear because of sticking to the glass walls Really neither of the conceptions is absolutely correct The extravasated platelets undergo a series of changes resulting in their disintegration Agglutination and adhesion are among these changes As the direct enumeration of platelets sticking to the glass walls is impossible, we are at the present moment unable to decide how much of the disappearance of platelets in vitro is due to their adhesion and how much to disintegration In a plaque of platelets adherent to a glass surface it is impossible to decide how many of them are intact The formation of substances with vasoconstrictor action during the coagulation of blood (O Connor H Freund) suggests a fairly rapid at least partial disintegration Wright's observation that higher concentrations of anticoagulants lessen the stickiness of platelets is in agreement with the findings of Bürker and others that substances inhibiting the coagulation of blood prevent also the agglutination and disintegration of platelets, and supports the opinion that adhesion and disintegration are two stages of the same process

Although from Wright's interesting investigations it is evident that a considerable number of platelets adhere to the glass walls and are incompletely if at all disintegrated, we feel justified for the sake of simplicity, in calling our test the "disintegration test' of blood platelets We have shown with our method that hæmophilic platelets have a normal "disintegration" velocity This finding disproves a conception of Howell's which has later been abandoned by Howell himself The only condition in which at that time the disintegration was found to be absent, very slow or delayed was in thrombocytopenic purpura Later I described a case of chronic thrombocytopenic purpura in which after adrenalone treatment (Klima) the platelets rose to 1 million but their disintegration was still absent The clinical symptoms were not improved In the last three years the velocity of platelet disintegration has been determined in the Children's Hospital Birmingham in a series of cases with hæmorrhagic manifestations by me by Dr T W Lloyd and recently by one of my laboratory assistants Five cases of hæmorrhagic disease with normal or only inconsiderably reduced numbers of platelets and absent or retarded disintegration were found One had a hæmolytic anæmia one a severe hæmorrhagic disease of the newborn, one a purulent peritonitis (all three with prolonged bleeding and clotting time) and two were clinically typical cases of Werlhof s disease with prolonged bleeding and normal clotting time but with 120 000–150 000 and 220 000–250 000 platelets respectively

Horwitz has improved our method using the counting method of Flossner-Hoffmann He has confirmed all the observations published in our first paper Shortly afterwards important work on the function of platelets was done by Morawitz and his pupils Jürgens used the agglutination as a test for platelet function and Morawitz himself has constructed an apparatus for determining the formation of a platelet thrombus By means of that apparatus the real nature of a familial hæmorrhagic diathesis observed in Finland and described by Willebrand has been elucidated Unfortunately there are no definite morphological signs of a functional deficiency of platelets The only certain fact seems to be that platelets with signs of immaturity (large forms with basophilic plasma, Ogata's tails) are also functionally deficient Glanzmann who was the first to put forward the conception of a functional disturbance of blood platelets based that idea on morphological findings which unfortunately are contestible His idea however, proved to be true as the functional tests have later shown In recent years several cases have been described with hæmorrhagic manifestations and extremely large numbers of platelets They have been called hæmorrhagic thrombocythæmia In a few of the papers photograms are reproduced of blood films in which not only the large number of platelets can be seen but also that they are not agglutinated thus more resembling a magnesium sulphate film than an ordinary blood film We regard it as probable that in that condition the platelets are functionally deficient their susceptibility to agglutination being reduced

The Children's Hospital, Birmingham H S BAAR

WHEN TO TIE THE CORD

SIR —Regarding your reference to Barcroft's experiments influencing the time when the cord should be tied I would like to put forward the following suggestion If oxygen lack as shown by Barcroft is the stimulating factor in promoting respiration surely it means that oxygen is normally cut off at the end of the second stage, and it therefore matters little how early or late the cord is tied from the aspect of apnœa in the fœtus

As for blood loss to the fœtus I do not agree with Mr. Chisholm s argument first because he considers that bleeding takes place from the fœtus into the placenta until pulsations in the cord cease and secondly, because he states that the only propelling force of fœtal blood from the placenta is the fœtal heart He suggests that the cord should be tied earlier because of the risk that the fœtus will lose blood in two ways by bleeding into the "placental lake" and by actual bleeding from the placental surface at the time of separation It is difficult to decide how much blood does actually enter the placenta at the end of the second stage Because the cord is pulsating it does not follow that blood is flowing in it, but merely that the pulsations are transmitted as in any other fluid medium (If an artery is tied, it still pulsates on the proximal side of the ligature until obliterated by the relatively slow process of thrombosis) Mr Chisholm himself infers that, because the inert placental lake may offer such resistance that the fœtal blood-pressure is largely overcome, therefore there is little or no venous return I suggest that the whole crux of the case is the fœtal arterial blood-pressure versus the passive resistance offered by the placental channels, which at this stage are greatly narrowed by shrinkage of the placenta following reduction in size of its surface of attachment to the now almost empty uterus The "intraplacental blood-pressure" must also by this means be greatly increased and thus add to the resistance of blood flow from the fœtus If this is so, the increased intraplacental pressure will mean increased venous return to the fœtus, as well as decrease or cessation of blood loss via the umbilical artery

So we arrive back at the question of when to tie the cord, not from the point of view of the presence or absence of pulsations in it but of how long it will take the *placental venous pressure to equalise the fœtal venous pressure*—i e, how long it will take the placenta to empty itself into the fœtus I have always tied the cord rather as a routine procedure than as a carefully premeditated step influenced by the immediate state of the fœtus or a remote one of the infant At the end of the 2nd stage the exchange of blood gases between maternal and fœtal blood must be negligible, owing to the greatly limited uteroplacental circulation caused by the retracted uterine muscle For this reason, I cannot see why apnœa in the newborn fœtus can be appreciably influenced by tying or not tying the cord early What it does influence is the amount of blood returned to the fœtus by the placenta by virtue of its own raised venous pressure, but that there is an appreciable intraplacental pressure is easily shown by the gush of blood which follows removal of the hæmostat from the placental end of the cord

Mr Chisholm's second point, concerning the blood loss to the fœtus from the placental surface at the time of separation, depends on how early the placenta separates, which usually does not happen until after the cord has been tied even by those who "stand and wait" before tying it

To summarise (1) Apnœa of the newborn fœtus is uninfluenced by the early or late tying of the cord (2) The amount of blood gained or lost via the placenta in the 3rd stage depends more on the intraplacental blood-pressure and the time allowed before tying the cord, than on the presence or absence of pulsation in the cord (3) The fœtus rarely has the opportunity to bleed from the placental surface

Seaforth, Liverpool ROBERT C PERCIVAL

HYPERTENSION

SIR,—We would like to reply to Dr Izod Bennett's letter of Nov 29 We did not suggest that Goldblatt's work indicated that hypertension was usually produced by a unilateral renal lesion We pointed out however that in a few cases hypertension and unilateral renal lesions coexisted, and that in some of these the hypertension has been relieved by nephrectomy Unilateral renal disease is frequently "silent," and although Dr Bennett states that each of the cases described in our article had localising signs from the very outset a more careful perusal of case 1 would show that this was not so It is on this account that we suggested that since in some cases there appears to be an ætiological association (not explained by Goldblatt's work) between hypertension and unilateral renal disease, and since a unilateral renal lesion may be otherwise symptomless, it is most reasonable and humane whatever the financial cost to exclude such a lesion by a complete urological investigation That this should be carried out in all cases is perhaps an overstatement, but it seems that this is necessary in order to disturb the complacency with which so many clinicians seem to regard this very common disease

G O RICHARDSON,
G A SMART

CRUSH INJURIES

SIR,—The ill effects of "crush syndrome" have been ascribed to the liberation of toxins from the trapped limb after its release It has been suggested that the application of a tourniquet to the limb before it is released, above the site of compression, might prevent this There is another sequel of such an injury which might almost be called "release syndrome" Here the patient remains comparatively well and cheerful while trapped, but dies suddenly soon after release, presumably because of an even more violent flooding of the system with toxins It would be interesting to hear whether M O s of mobile units have experimented with tourniquets In the raids of last autumn many patients were not reaching hospital alive or w soon after admission, and it might well be tourniquet would have saved them

Highgate R L BE

ANÆSTHETIC FLOWMETERS

SIR,—With reference to the note on flowme gas or liquid in the *Lancet* of Dec 6 (p 718) I ma forthwith that I make no claim to have been to suggest the use of rotameters for anæsthetic g *cannot be accused therefore of any attempt to s* thunder of Richard Salt of the Nuffield Depart Anæsthetics Nevertheless, in recognition of v help extended to me in the past by instrument I feel that the moment is opportune to rec following facts

In 1928 Messrs Siebe Gorman & Co Ltd flowmeters of the rotameter type to my speci for N_2O and O_2 After clinical trial these flo were fitted to an anæsthetic apparatus made for Messrs Allen and Hanburys in the same year In following an inquiry from Mr A Charles King, Rotameter Company offered to make rotameters N_2O and O_2, calibrated for anæsthetic purposes [illegible] informed that the original correspondence bet[illegible] Mr A Charles King and the Rotameter Company [illegible] in existence While it is more than probable [illegible] rotameters were used in connexion with anæsthesia in Germany before 1932 it is thus apparent that in England the possibility of using them for anæsthetic purposes was mooted before 1937, and by Mr A Charles King

Harley Street, W 1 I W MA[illegible]

Parliament

ON THE FLOOR OF THE HOUSE

MEDICUS, M P

THE *parliamentary week under review began* with the declaration of war against Japan on Dec 8, included a statement by the Prime Minister on the war situation which is to be the subject of a debate, and was filled u with the second reading, committee stage and third reading of the National Service Bill No 2 In the House of Lords the first and second readings of the bill took place and it will pass into law at once Provision was made during the week for a debate on the allowances granted to the dependants of the men in the services There was also a debate fixed on a Supplementary Vote of Credit for War Expenditure and for the passage of a special Consolidated Fund Bill through all its stages

* * *

The impact of such tremendous events as the extension of the war to the Far East and the Pacific Ocean, the virtual mobilisation of the whole nation for war purposes and the further drawing of astronomical sums of money for war expenditure are rather stunning in their effect o parliamentary practice But criticism and the norma work of Parliament continue The Prime Minister was able to clear up a little parliamentary storm which grew out of a misunderstanding of the effect of the new bil on M P s of the age-groups called on to serve It has i fact been the recognised practice for some time to leave i to individual M P s to judge where their duty lies an whether they should serve in the forces or in Parliament It has also been the practice that an M P in the force wishing to be freed to devote himself to parliamentar duties is given this freedom But some members wer not aware of this as these *rules and practices* had not bee embodied in a considered statement

The Prime Minister made it clear that while it woul not be appropriate to confer on members a statutor exemption from the obligations they share in commo with everyone else they have also "the high duty" o service in the legislature They are therefore given free choice by virtue of their position as Members o Parliament and not as a favour

* * *

Mr Bevin as Minister of Labour in charge of th National Service Bill has done a long and difficult jo effectively within the limits imposed by the form of th but there have been some breezes one of which ed Mr Henderson Stewart, who had made certain icisms of the A T S The words he used were, "We r in this House and in the Lobbies the reports of lical officers about the conditions in the camps re is not a constituency of which I have ever heard t has not this general but very definite impression t the A T S is not the sort of Service to which a nice goes" Sir Percy Harris interjected "Hear Hear," Mr Stewart continued "My right hon friend has parently had the same experience" and called on the r Office to do something drastic and on Mr Bevin to e drastic measures to remove "these unfortunate nditions' Mr Bevin's reply to this was to say, "Why there concerning the A T S the assumption that cause women are drafted somewhere, immorality is und to ensue? That is a lot of unutterable nonsense I say that the conduct of our young people during s war has been cleaner than in the whole history of our untry"

Mr Henderson Stewart at once protested, "I was not r one moment thinking about morals I was thinking bout the physical conditions in which they live I ink the morals are excellent" Mr Henderson Stewart hould have used plainer words about the lack of proper amp accommodation and dirt in the A T S quarters nd it is unfortunate that this suggestion of immorality mong the A T S was dragged into the debate through misunderstanding The facts are all against it What is true and what needs improvement is the arrangements for the comfort of A T S, including lavatory and washing accommodation But this is also true of the W A A F s—as Mr Bevin indeed suggested After this little fracas Mr Bevin went on to speak of the provision of hostels and welfare arrangements but as these matters are outside the scope of the bill they could not be dealt with by amendment

What did come out of the debate is a bill which will be an act by the time these words are in print That act gives the Government very drastic powers over the whole population and especially over the age-groups 18–65 In the original discussion of the Maximum Effort resolution tabled by the Government the Speaker described this as a de-facto "first reading" discussion of the bill But it turned out to be nothing of the kind The bill is limited to powers over persons The provision of welfare and medical services is not touched and could not be discussed They are left as far as legislation is concerned to some date in the future and there is uneasiness about them in the minds of members

Another matter left out of the act—although adumbrated in the original Government resolution—is the position of young people from 16 to 18 These young people are to be looked after and directed as to their activities and there was some suggestion that they should be under the services This suggestion was contested and the "direction" is to be through the Board of Education and voluntary youth societies It is all rather vague but the situation is to be explored in a debate on the adjournment at an early date But if youths of 16 are eligible for Home Guard duties and the Air Training Corps it is hardly clear how the services can be kept out or whether they should be kept out The nation even at this stage has not got really used to total war We don't like young people being drawn into the war But perhaps the best we can do is to keep the control of any "direction" in the hands of the Minister of Education And these directions will have to be carefully considered for it is on the shoulders of the youth of today will lie the heavy responsibilities of directing democratic opinion in the decade after the war

FROM THE PRESS GALLERY

National Service Bill

IN the debate on this bill in the House of Commons it was pointed out, almost fearfully, that in conscripting our women we are "actually taking the initiative," for the Nazis have failed in the attempt, and noble Lords in the upper house thought the bill was "a tremendous compliment to democracy" Both houses were anxious that the Government should recognise that there would probably be a higher rate of sickness, breakdown and discharge among the men of the age-group 41–51 than among their juniors Sir E GREGG promised that their duties would be carefully allocated according to their medical grade, but it was generally felt that the Government should consider the pension claims of these men sympathetically

Moving the second reading of the bill in the Commons Mr E BEVIN confessed that the human is the most awkward animal of all to handle, but proved himself adroit in the management of his colleagues He gave an assurance that one woman doctor should be present at the medical examination of women He also gave a pledge that if a man has been discharged on medical grounds he will not be called up again, but would be directed into industry Mr T M SEXTON urged that when women left home to work in another district they should register at once with a panel practitioner in the new area Sir FRANCIS FREMANTLE called attention to the need to safeguard the water-supplies of the country Water undertakings must be allowed to keep some of their skilled personnel Dr HADEN GUEST asked the minister to give some indication of the provision he would make for hygienic and medical supervision in the new factories There was a shortage of medical manpower and they would not get what they wanted unless they had the whole medical services of the country pooled Mr BEVIN replied that he could not deal with the nationalisation of the medical services by this bill, they were constantly being expanded and he had early made a great innovation by introducing a compulsory medical service in industry, which now included nursing Mr R DAVIES said the bill had as its background the population problem, and asked what effect the conscription of women would have on the birth-rate

In the debate in the Lords on Dec 12, Lord MOYNE was able to reassure Lord GREVILLE about the provision of domestic staff for hospitals Last week Lord Greville complained that these workers were steadily seeping away Now an order is to be made laying down that no woman between 20 and 30 working in a vital industry—which includes hospital work—may change her employment except with the approval of the Minister of Labour

War-time Nurseries

At the cinema the news reel informs us that we "live in the presence of history" Against this background the question "What to do with the children" may seem trivial But as Lord NATHAN pointed out in the House of Lords on Dec 9 when asking the Government what provision they were making for war-time nurseries, the need for an answer is urgent if we are to make full use of our woman-power. Industry is dependent on what might be called immobile mothers, and it is essential to morale that women should have confidence that the arrangements made for their children are adequate Minders are no doubt all very well, but he reminded his peers that children under five are brittle It had been stated that by the early part of next year 500 nurseries would be open, taking an average of 40 children each, or 20,000 in all But Lord Nathan suggested and he believed that it was an understatement that 200,000 children would have to be provided for, and provided for at night as well as in the day And what was to be done about the children between five and fourteen during school holidays when their mothers were at work? The Government were confronted with a great social problem Upon the right solution depended the health and happiness of the generation for which we were fighting

Lord SNELL acknowledged the Government's responsibility for what was a human as well as an industrial problem He did not suggest that the figures given by Lord Nathan were exaggerated, because no-one at present could estimate what the intake of married women into industry would be, but the Government's answer was that first it was necessary to observe the rate of intake and then to try to provide sufficient nurseries to meet the demand, but instructions had been given to local authorities to prepare for the expected need and to be ready for quick development The Ministry of Health, the Ministry of Labour and the Board of Education were collaborating closely in this matter and so were the local maternity and child welfare and the education authorities At the end of November 194 nurseries were in operation, and a further 209 approved but not yet in full action, providing for something over 15,000 children A further 264 were in active preparation and the Government felt that this programme was fairly satisfactory But Lord **Nathan** said that neither he nor the other Labour Lords could agree It might be sound policy to observe the intake of married women into industry and then take action if this matter were being dealt with as one of child welfare in a scheme of social readjustment But the problem was to get the mothers into industry, and the provision of accommodation for the children is the inescapable precedent for these women going into industry at all He therefore hoped that the Government would ensure that steps were taken in advance of the intake and did not lag behind it

QUESTION TIME

Inspection of Mental Defectives

Mr H C **Charleton** asked the Minister of Health the number of visits made by the commissioners and inspectors of the Board of Control to mental defectives under statutory guardianship in the administrative area of the county of London during each of the 12 months ended michaelmas in the years 1939 and 1940 —Mr E **Brown** replied The numbers of visits by commissioners were 98 and 0 respectively, and the number of visits by inspectors were 35 and 4 respectively Article 83 of the Mental Deficiency Regulations, 1935, permits but does not require visits by commissioners or inspectors and arrangements have been made to visit all cases placed under guardianship in the years 1940 and 1941 and establishments where there are a number of mental defectives under care I am informed by the London County Council that their officers have duly made the visits prescribed by Article 86 of the regulations —Mr **Charleton** Is the Minister not aware that the figures he has given reveal a serious evasion of duty by the Board of Control ? How can the commissioners carry out their duties to these unfortunate people if they do not see them and understand their condition ? Is he aware that there is evidence that some have not been visited for a number of years ? Is he aware that the figures in 1939 should have been in the neighbourhood of 550 and in the next year 500 ?—Mr **Brown** The commissioners were working under great difficulty and as he knows the inspectorate has other duties to perform in addition —Mr **Charleton** Does the Minister not see that the first duty was during a prewar period when there were no difficulties ?

National Wheatmeal Loaf

Sir **Ernest Graham-Little** asked the Parliamentary Secretary to the Ministry of Food to what proportion of the population the white loaf, fortified in accordance with the undertaking given in July, 1940, was now supplied , what proportion of the consumption of the national wheatmeal loaf now bore to the total consumption of bread in this country , what had been the expenditure to date by the ministry in advertising the national wheatmeal loaf, and whether the Ministry had now abandoned or diminished such advertising —Major G **Lloyd George** replied Figures relating to the proportion of the population to whom the fortified white loaf is now supplied are not available, but approximately 25% of the white bread and flour consumed in the United Kingdom is now being fortified with vitamin B_1 It is estimated that 7% of the bread consumed is in the form of the national wheatmeal loaf The expenditure to date on advertising national wheatmeal is £29,000 The advertising has included many thousands of posters which are displayed in all parts of the country The use of national wheatmeal bread and flour forms an important subject in the ministry's food advice service to housewives The ministry has not abandoned this advertising but there is a wide range of subjects to be covered in the space available for the ministry's , consequently there are periods during which there is space for no more than occasional mention of wheatmeal in advertisements primarily devoted to other subjects

X-ray Examination of Recruits

Sir **Francis Fremantle** asked the Minister of Labour whether he had considered the adoption by medical boards of X-ray examination for tuberculosis of every recruit, in the light of American experience, and in the interest of those found to be affected and of Exchequer liabilities —Mr **Ernest Bevin** replied This suggestion was fully considered last year by the Medical Advisory Committee under the chairmanship of Lord Horder, and the committee decided that its adoption was impracticable I am advised that this

here ?—Mr **Bevin** I understand that at the time it question of preparing a complete supply of equipment

Increase in Juvenile Delinquency

The number of persons under 17 years of age found guilty of offences in England and Wales has in since the war by about 30% (Mr H **Morrison** replying Mr D L **Lipson**)

Certificates in War-time

In answer to a question Mr **Brown** said I have asked by the British Medical Association to consider w steps can be taken to reduce the demands made on medical profession for certificates in connexion with activities A conference took place between repre *of Government departments and of the association at w* the whole matter is now being considered by the de individually with the object of reducing to a minimum number of purposes for which medical certificates are to be required

Suspension of Dudley M O H

Captain G S **Elliston** asked the Minister whether he proposed to intervene on behalf of the M O H for Dudley who had been suspended for the duration of the war because he had registered as a conscientious objector, as permitted by the Military Service Act —Mr **Brown** replied The appointment, dismissal or suspension of the M O H of a county borough does not require my approval and I have no authority to intervene between the council and their officers in this matter

Diphtheria and Immunisation

Sir F **Fremantle** asked the Minister whether he had any statistics of the results of immunisation against diphtheria in New York, Chicago and Toronto as compared with London. —Mr **Brown** replied In New York City, since large-scale immunisation of children began in 1929, diphtheria has steadily decreased from an average of about 10,000 cases year during 1920–29 to just over 400 cases in 1940, in relatio to a population of over 7 million Information about Chicag is not readily available In Toronto in the five years durin 1933–37 there were no more than 209 cases of diphtheria in al In two of these years, 1934 and 1937, there was not a sing death, while in 1940 there was neither a notification nor death In the county of London, with a population of abou 4 million, notifications of diphtheria in recent years hav averaged close on 8000 cases a year

Committee on Nurses Salaries

In reply to a question from Miss M **Lloyd George** Mr **Brown** said The committee on nurses salaries held its firs meeting on Nov 27 It is my intention that the committee scope should extend to nurses possessing or in training f the certificate of the Tuberculosis Association, and that should also extend to health visitors Before the scope so extended it may be necessary to make some adjustmen in the committee I have decided to set up a separa committee to draw up agreed scales of salaries for midwi on a national basis Lord Rushcliffe will act as chairman the committee for midwives as well as of that for nurse Some nurses and midwives posts involve the practice bo of nursing and of midwifery and I shall request the committ to consult together before making recommendations abo these overlapping matters

Leprosy in the West Indies

Mr G H **Hall** in reply to a question from Dr H **Morgan** gave the following table setting out the incidence leprosy in the British West Indies

Colony	Year	New cases	Total cases	Populati
Bahamas	1940	3	17	70,3
Barbados	1939	5	63	193,0
Jamaica	1939	N S	249	1,195 4
Turks and Caicos	1938	2	5	53
Antigua	1940	N S	6	36 07
St Kitts	1939	3	59	37,9
Montserrat	1939	N S	N S	13 5
Virgin Islands	1940	N S	N S	61
Trinidad and Tobago	1939	77	377	473,4

Obituary

FRANCIS HENRY MOSSE

M R C P.

ARLY this year Dr Mosse who had been working as a ical missionary in China since 1920 fell ill with erculosis and was sent to America for treatment seemed to be making good progress and his death on 6 after an operation was unexpected Robin se, as his friends called him was the son of the Rev H Mosse, vicar of St Paul's, Covent Garden He educated at King's School Canterbury and Trinity llege, Oxford and qualified from King's College spital in 1913 During the last war he served as ptain in the R A M C in Egypt and Palestine and was th General Allenby s forces at the capture of rusalem His heart was set on medical missionary ork, and after taking the M R C P he sailed for China nder the S P G , to take up the post of physician at the eloo Christian University at Shantung, in North ina Here for twenty years Mosse trained young hinese men and women— A picked group of the finest udents in the world " he called them He counted imself " the happiest man in Asia " to be allowed to erve them, and he worked with them in refugee camps n times of flood and famine, as well as in the lecture alls and wards of Cheloo Hospital After the Japanese ccupation of North China most of the 4000 students at Cheloo trekked west to free China but the hospital emained and Dr Mosse stayed with it He leaves a widow and two daughters who are in the United States

ELWIN H T NASH

M R C P , D P H

THE loss of Elwin Nash brings a flood of memories Nash was no ordinary official The fire of the enthusiast burned brighter in his eye as each year added to his age It was in fact in the later years of his life that he really found his feet and became a pioneer in public health One of the particular qualities for which we admired him was his practical mastery of the improvements he advocated Years ago he came to the conclusion that many of the nutritional problems of the nation would be solved if it were taught to buy better and to cook more skilfully He wrote a book on the subject and sold it at a price which the poorest could pay And before writing it he went into the kitchen and became a first-class cook himself For him armchair administration did not exist ' I attend at one welfare clinic and at one school clinic regularly every week " To know that a thing was good and needed in public health was sufficient to awaken his determination that his district should pioneer He was one of the first to commence immunisation against diphtheria on a large municipal scale the records he kept were meticulously accurate One day a dentist spoke to him of the disastrous effects in appearance and in health that could arise unless children's teeth were carefully regulated What was good enough for Park Lane was good enough for Heston and Isleworth and he started a clinic where the poorest in his district could obtain orthodontic treatment Elwin Nash just could not let disease go untreated He gave a lecture on myxœdema at the Society of M O H 's and confessed how he had secured his patients " I saw them in the bus, I saw them in the train and in the street I stopped them and secured treatment for them if I offended against ethical canons, I place myself without reserve in the hands of you who are my colleagues and friends " He was an enthusiast and a fighter Yet big, burly and determined no-one had a gentler touch with children, they trusted him and realised he would look after them as individuals—just as in the bigger realm of public health his council trusted him to look after them as a community

Cromwell Studios Hounslow

D H G

Elwin Harral Thomas Nash was born in 1872 in Guernsey the eldest son of Joseph Nash, R I He was educated at St Paul's School and St Thomas s Hospital, qualifying in 1896 after which he filled a series of house-appointments in London and the Home Counties and assisted in several departments at St Thomas's Then for a while he was in general practice at Accrington, but after taking the D P H at Manchester and holding a public-health research scholarship he went to Derby to assume charge of the isolation hospital became assistant M O H there and then M O H of Wimbledon, finally ending up at Heston and Isleworth In 1938 just after his retirement the society of M O H 's elected him president, and at their annual banquet he foretold amazing developments in the growing association between practitioner and health officer which he did much himself to foster Many of the high lights of his work have been noticed in these columns, among the more recent an early venture (1934) in the use of adult serum to modify measles in fever hospital contacts a forecast of planned obstetric practice (1937) and some indication of the aim and purpose of ' Dr Nash's Cookery Book ' In 1899 he married Mary Monica Oldershaw who survives him with four sons and a daughter

ERNEST JOHN FRANK HINDE

M R C S , CAPTAIN R A M C

IN a recent casualty list it is announced that Captain E J F Hinde has died of wounds He was born in 1912 the eldest son of Dr E B Hinde of Norwich and was educated at Gresham's and Emmanuel College Cambridge where he won his athletic colours At Guy's he played hockey for the hospital and occasionally ran but here his keenness for his work left him little leisure He qualified in 1938 and the following year obtained a house-appointment at Guy's but soon after the outbreak of war he resigned to join the R A M C He served at first with the East Anglian field ambulance, as his father had done in the last war, and afterwards with another field ambulance Later he volunteered for foreign service and it was on his way abroad that he met his death at sea He married Miss Norah Steeds in 1940

Polyfoto

ANTONY FLEMING BALDWYN

M B LOND FLYING-OFFICER R A F

Flying-Officer Baldwyn has been reported missing but is presumed to have lost his life on active service in the Middle East He was the eldest son of the late Captain C F Baldwyn He entered St Bartholomew's Hospital in 1935 and took his London degree last year at the age of twenty-two and joined the R A F after six months as house-physician at the base hospital of the Bart's sector One of his friends writes Baldwyn showed aptitude for learning new things quickly and he applied his knowledge for his patients He was good at most games and could sail any sort of boat

DAVID ROBERTSON TAYLOR

B A CAMB , M B, EDIN D P H

Dr Taylor who died at his home in Belfast on Nov 8, was the only surviving son of the Rev D A Taylor D D of the Presbyterian Church in Ireland Born in 1870 Taylor was educated at the Royal Belfast Academical Institution and Cambridge University where he took his degree in 1901 He proceeded to Edinburgh University and graduated M B in 1906 *After* service in the R A M C he obtained the D P H at the Queen's University of Belfast in 1918 He was a medical referee under the National Health Insurance scheme in Northern Ireland, and was engaged in general practice until the day *before his death* In 1903 he played rugby for Ireland, but cricket was his enduring passion and he played for Gentlemen of Ireland in 1924 An accomplished musician he was an enthusiastic member of the British Music Society of Northern Ireland David

Taylor's qualities of simplicity and modesty won him many friends and his unfailing gentleness and kindness were valued by his patients He leaves his widow with two daughters

DERMOT HARRY TUTHILL DUGGAN

M D DUBL , SURGEON LIEUTENANT R N V R

Surgeon Lieutenant Duggan, who was reported missing in August 1940, is now posted as missing, believed killed in action He was serving on H M S *Ardent* which took part in convoying troops to Narvik and was lost in battle off the coast of Norway in June 1940 He was the only surviving son of the late Captain George Grant Duggan, who was killed at Gallipoli in 1915 Duggan was educated at the Imperial Service College Windsor and entered Trinity College Dublin in 1929 He graduated in arts in 1933 and in medicine in 1935 He was an active member of the Dublin University harriers, of which his father had once been captain He passed his examinations punctually and after qualifying in the minimum time he held house-appointments at the Fermanagh County Hospital, Enniskillen, and at the Kent County Ophthalmic and Aural Hospital, Maidstone He also travelled to New Zealand as surgeon on the s s *Durham* In 1939 he was granted his M D for a thesis on chemotherapy in acute ear disease which was later published in the *Irish Journal of Medical Science*

Medical News

Royal College of Surgeons of England

At a meeting of the council of the college held on Dec 11, with Sir Alfred Webb-Johnson, the president, in the chair, Mr Seymour Barling was reappointed representative on the court of governors of Birmingham University, Mr L E C Norbury as representative on the Central Council for District Nursing in London

Diplomas of fellowship were granted to the following candidates —

Royal College of Physicians of Edinburgh

At the annual meeting of the college on Dec 4, Prof Charles McNeil was re elected president and the following council was elected for the coming year Dr R B Campbell, Dr L H F Thatcher, Prof D M Lyon, Dr A G Ritchie, Prof L S P Davidson and Dr A Rae Gilchrist Professor Lyon was nominated vice president

First Polish Graduates in Edinburgh

There was a historic addition this year to the small winter graduation at Edinburgh University on Dec 12, when the first degrees were conferred on students of the Polish School of Medicine at the university Sir Thomas Holland, the vice chancellor, presided and the degrees were conferred with the authority of the Polish government by Prof A T Jurasz, dean of the Polish faculty of medicine The new Polish graduates were Miss Jadwiga Mickiewicz of Warsaw, Second Lieutenant Stanislaw Schta, Asp Wladyslaw Kazimierz Gatuszka and Asp Ferdinand Solich, all of Cracow

22nd General Hospital R A M C

The fifth week end course in war medicine will be held at this hospital on Jan 3 and 4 The visiting lecturer at this course will be Mr H Morriston Davies

Medical Honours

The M B E has been awarded to Dr W L M Bigby

Dr John Findlay

Dr Bigby who is assistant medical officer for civil defence Southampton has worked long hours helping to extricate tra people and has several times entered wrecked buildings to re the suffering of the injured

Dr Findlay, who is in charge of a first aid post at Peterh was thrown to the floor and injured when a bomb burst but grave risk to himself he crawled under debris and gave inject to three casualties

Posthumous Honour

The Royal Meteorological Society has awarded the Sym gold medal for 1942 to Dr J S Owens, whose death recorded in our columns last week

King Edward's Hospital Fund

This year the fund is again distributing £300,000 amo the voluntary hospitals of London The fund is now propo ing, with the help of the Nuffield Trust, to extend the work o its nursing recruitment service to provincial training school

West Ham Practitioners Coordinating Committee

The discussion group of this society will meet for the fir time on Tuesday, Dec 23 at 2 30 P M , at the Y M C A Hal Woodgrange Road, Forest Gate, E 7, to consider the exten sion of the panel system versus an all out state medi service Dr A V S Davies will speak in favour of a extension of the panel system, and Dr R N Brandwood wi advocate a state medical service Practitioners from adjoinin areas are invited to attend

Births, Marriages and Deaths

BIRTHS

ARTHUR —On Dec 1 at Wolverhampton the wife of Squadro Leader Hugh Arthur F R C S E , R A F V R —a daughter

BONNELLA —On Dec 11 at Oxford, to Dr Gertrude Bonnella (n Afoumado), wife of F George Bonnella, of Chinnor— daughter

BOLAM —On Dec 7, at Gosforth Newcastle on Tyne the wife Dr Mason Bolam—a daughter

BRYAN —On Dec 4, at Plumstead, Capetown, the wife of Dr T B Bryan—a son

DANIELS —On Dec 13, at Grantham, the wife of Dr Marc Dani —a daughter

LUNN —On Dec 12, at Guildford the wife of Captain H Fletch Lunn R A M C —a daughter

RIORDAN —On Dec 7 at Newcastle on Tyne, the wife of Capta T P Riordan, M B R A M C —a daughter

SODDY —On Dec 13 at Cambridge the wife of Temp Majo Kenneth Soddy R A M C —a daughter

THOMAS —On Dec 3, at York the wife of Dr Rene Thomas— daughter

MARRIAGES

CUDDIGAN—REDFERN —On Dec 10 at Ripley, Simon Thom Cuddigan M B to Betty Redfern

DUFFY—BOWERS —On Nov 29, at Chichester, Charles Allan Gav Duffy, M R C P , captain R A M C , to Margaret Marian Lucy Bowers

ELLIOT—HICKS —On Dec 9, at Blockley, Glos , Thomas Ell Elliot, F R C S E , major R A M C , to Mary Catherine Hic

DEATHS

CARMICHAEL —On Dec 7, at Lahore, John Carmichael, F R C S lieut colonel, R A M C retd of Srinagar, Kashmir aged

MOORE —William David Moore, M B Edin , captain, R A M aged 43

Notes, Comments and Abstracts

THE STUDENT ON HIS STATE

e British Medical Students Association which is only national organisation claiming to represent al students and has the status of a faculty com- s of the National Union of Students has been d by the Medical Planning Commission to draw up morandum on the reform of the medical curriculum der that opinion may be as nearly unanimous as ible when the memorandum is drafted the B M S A est that special committees should be set up in the rent medical schools to organise wide discussion and l in reports To make this easier the B M S A e drawn up an outline,[1] summarised here, of some of points which it is hoped to cover

he *emphasis, in medical education should be on the* enance of health and the prevention of disease rather r on cure No suitable student should be debarred from heme for financial reasons, and all medical schools should open equally to men and women A state medical mination might replace the varying examination standards existing More full-time salaried teachers should be pointed Vacations for students might be reduced in the clinical years, but should be at least six weeks annually ring the clinical years

The premedical course should provide a broad scientific *Thus* biology should be taught as a general study of e rather than as a detailed study of a few forms representing ended ends of evolution chemistry and physics should taught with more emphasis on general principles, and the rse might be widened to include the elements of sociology nthropology and genetics In the preclinical years there hould be more emphasis on scientific and experimental ed the teaching of anatomy and physiology should be rdinated, and there should be more attention to the developmental approach and to surface anatomy clinical cases should be used to illustrate anatomical and physiological principles

During the clinical years the teaching of hygiene should be incorporated in a fuller course on preventive medicine, and hological medicine should be taught more thoroughly A course in general pathology should be completed by the end of the first three months of clinical work Clinical instruction should be organised for small groups rather than large classes, and the basic teaching should be in the form of tutorial If attendance at them is compulsory, means must be devised to ensure that the standard of formal lectures is maintained The value of the clinical material in hospitals under the sector and regional schemes is appreciated, and the aim after the war should be to extend still further the number of hospitals in which experience can be gained Finally, a hospital education is not felt to be enough; students should get experience of general practice either by a system of apprenticeship to selected general practitioners or by a dispensary system similar to that in operation at some Scottish medical schools

The B M S A suggest that members of the various medical schools besides sending in additions to or criticisms of the outline should review the system of education at their own schools, indicating the hours spent at lectures and ward rounds in the wards and in the outpatient departments and giving their experience of the value of work in base and evacuation hospitals; and should send in a detailed account of the reforms they would like to see in their own schools

THE DIABETIC FRONT

THE diabetic clinic of University College Hospital has published a handbook giving its war-time diets and instructions for diabetic patients (Diabetes in Wartime London H K Lewis and Co 1s) Prof H P Himsworth's hand is evident in the book although his name does not appear The booklet sets out the rules of the Food Ministry dealing with extra and substitute rations for diabetics and gives practical advice on special identity cards and discs precautions against shortage of insulin and interruption of routine by air-raids evacuation and the like The usual advice to send for medical help promptly when a diabetic develops a complicating illness is emphasised and the patient is told what to do about food and insulin if the doctor is delayed The diets are adapted to the present rationing scheme and range by steps of 250 calories from 1500 to 2500 calories Two skeleton diets are given at each level and a substantial list of alternatives is added at the end The content of these diets in calcium and vitamins A B_1 and C is well above the accepted standard requirements A 1000-calorie diet for use during recovery from coma and another for the temporary invalid or convalescent are also included The book ends with half a dozen recipes for puddings and a ruled sheet on which the patient can keep notes of his diet insulin dosage and weight There is only one criticism the diets aim at a high standard of precision in weighing and no alternative household measures are given for those patients who cannot be expected to weigh ' an extra ¼ oz bread and an extra ⅛ oz butter "

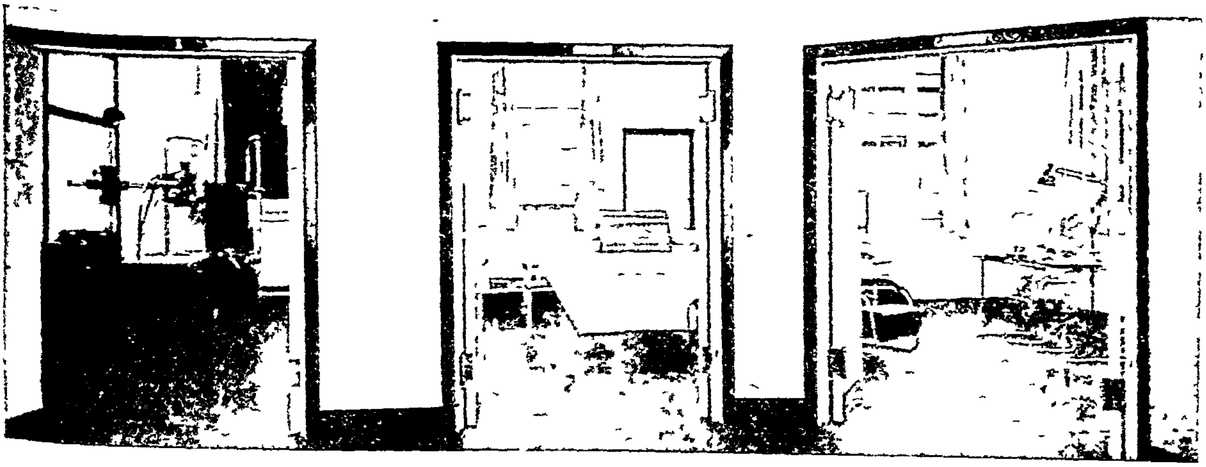
THE AUSTIN MEDICAL DEPARTMENT



The new resuscitation and treatment rooms opened by Sir David Munro at the Austin works Birmingham on Dec 3 The new department also contains treatment rooms for men and women a bathroom an examination room a consulting room, a laboratory doctors' rooms and an office for clerical staff and record filing, it is staffed by three doctors and a nurse with experience of radiography, and serves the 25 000–30 000 workers employed The medical officers will investigate health problems and occupational illness give immediate treatment for major and minor injuries and illness, undertake medical examinations, grade a man s work to his capacity after sickness, and supervise the nurses in charge of ambulance rooms throughout the works

HOW IT WAS DONE

NINE-TENTHS of general practice today is the care of panel patients and their dependants, but in a pleasant chatty book[1] Dr E A Barton recalls the conduct of medicine in the spacious manner now passing away—of general practice limited to the well-to-do in an exclusive neighbourhood Perhaps this is the very reason why it makes such good reading either for the doctor or the layman we rub elbows with great men and women of the past and we are not introduced to any social problems of the present That Dr Barton is a man of great age is evident, he was a fellow student of Rose Bradford and he once went to a dance in Hampton Court seated on the knees of his aunt in a sedan chair But his chapter on quacks will be of value to the contemporary layman, and that on medical etiquette to the medical profession And in connexion with etiquette he tells a story—proving that though medicine and practice alter human nature remains the same—about a man of highly strung neurotic temperament who explained with pantomime that he endured the agonies of the damned in the abdomen "His appetite was excellent he snored like a trombone—so his suffering wife told me—eight hours every night without turning but he suffered intensely There was nothing very much wrong with him physically but when a man is so ill as to think that he is ill when he is not ill then he is very ill" This man Dr Barton saved, not from the abdominal surgeon but from an abdominal physician a Dr X who saw nothing but duodenal ulcer in every stomach-ache for twenty years after this incident to the time of his death the patient "ate and drank anything, slept like the dead but suffered intensely if anybody asked after his pains" But then Dr Barton belongs to the days when it was considered the function of the doctor to protect not only the body, but also the pocket of his patient from the consultant who "conscientiously and seriously" thought as Dr X did With the development of investigations and operations not to mention psychotherapy the G P 's task is harder in this respect than it was forty years ago This book will make an excellent New Year present to a doctor, his relations acquaintances and patients

TEAM OF TWO

BREAST-FEEDING is admitted to be an important process whether from the viewpoint of nutrition or psychology The psycho analyst regards suckling as the child's first erotic experience and one which will leave traces later on his character and personality Dr Merell P Middlemore, whose work ceased with her untimely death, wrote her last book ("The Nursing Couple" London Hamish Hamilton Medical Books Pp 191 7s 6*d*) as an orthodox Freudian analyst, but its chief value may well lie in the detached observations of breast feeding which it records and in her original comments Careful observations of the behaviour of the suckling are scarce, as Dr Edward Glover points out in his foreword Dr Middlemore was fortunate in having the chance to carry out her study in the lying-in wards of a general hospital, and though this environment does not capture the atmosphere of the home it at least ensures that breast-feeding is conducted favourably from the nutritional point of view and thus cuts down psychological factors arising from faulty technique in feeding She watched an unselected group of mothers and infants during feeding, making no attempt at statistical study but recording clinical facts and found that there are trends in feeding behaviour which occur irrespective of the success or failure of the mother to give adequate nourishment She distinguished between satisfied and unsatisfied sucklings regarding as satisfied those who sucked steadily by the fourth day of life and took 2–3 oz at most feeds Those who were unsatisfied she grouped as "excited ineffective sucklings" and "inert sucklings", the inert group were further subdivided into the "simply inert" and the "irritably inert" Excited ineffective sucklings were fussy, either taking the nipple but failing to hold it or refusing it repeatedly for days, or changing their behaviour at every feed Sucklings who were simply inert were lazy from the start and failed to suck for some days irritably inert began actively but with many cap tricks and became drowsy after three or four showing a progressive distaste for the breast, which obviously failed to satisfy them Recovery from inertia might take place at a single satisfying f only gradually as the child began to take pleas feeding Dr Middlemore speculated on the cau irritable inertia, it might, of course derive f defect in the nervous arc of the sucking reflex, far more likely to develop from faulty conditio Clumsiness in putting the child to the breast or handling may associate sucking with discomfort in mind It is characteristic of this group of infants when they pass from the restless to the inert stage adopt a peculiar immobility which Dr Middle likened to the defensive immobility of some h animals it might she thought be an example of instinctive fear reaction—in this case fear of ro handling—used inappropriately, so that it worked the child's disadvantage Further analysis of her c and other studies on the same lines, may throw as m light on feeding difficulties as on mental and psych logical development

BACTERIAL CONTAMINATION OF CEREBROSPINAL FLUID

WILSON SMITH
D DIP BACT. MANC
ESSOR OF BACTERIOLOGY,
IVERSITY OF SHEFFIELD

MURIEL M. SMITH *
M.A. CAMB

SERIES of cases of meningitis in patients who had n subjected to spinal anæsthesia in the Sheffield ral Hospital was reported by Barrie[1]. Routine eriological examinations of the cerebrospinal fluids de throughout the epidemic had proved negative ept for three colonies of a gram-negative bacillus on e plate and towards the end of the series one of us was ed to investigate the condition. In a note contributed Barrie's paper we reported that circumstantial evince indicated a cold-water filter of the Berkefeld type the probable source of infection. This filter supplied ter in which the lumbar-puncture needles which had en previously sterilised by treatment with formaldeyde were rinsed before being used. The repeated olation of a small actively motile gram-negative acillus from samples of the water proved that the filter as faulty. The isolated organism was completely on pathogenic for laboratory animals; furthermore glutination tests with the sera of convalescent patients iled to yield any evidence that it was ætiologically lated to the outbreak of meningitis. Nevertheless no rther cases occurred after the filter had been put out of mmission.

We were able to obtain samples of cerebrospinal fluid from only two of the later cases. At the time attempts to isolate an organism from them by both cultural and animal inoculation methods were unsuccessful. A spare portion of one of the specimens however was stored in the ice chest at about 4° C and 16 days later was found to be slightly turbid from bacterial growth. Whether this organism was the causal agent in the series of meningitis cases could not be determined largely because of its extreme instability in suspension which made satisfactory serological tests with convalescent sera impossible. The facts that it failed to grow on all the usual laboratory media except peptone water and peptone-water agar and that temperatures above 30° C completely inhibited its growth, make it much more likely that it was merely an accidental contaminant. Further study left no room for doubt that it was a water organism originally derived from the filtered water used for rinsing the lumbar-puncture needles. While not identical with the bacillus repeatedly isolated from the water it was a closely related strain or species possessing similar morphological and cultural characters and showing some degree of serological relationship. Both organisms were small actively motile gram-negative cocco-bacilli in young peptone-water cultures; they became non-motile and extremely pleomorphic in old cultures, they fermented none of the usual carbohydrates reduced nitrates to nitrites and failed to produce indole. They could not be identified with any established species.

On inquiry we learnt that the practice of rinsing needles in sterilised water either to cool them quickly or for some other purpose is common in many hospitals. The results of the investigation of Barrie's cases indicated that this practice may not only lead to contamination of cerebrospinal fluid at the time of collection but may even constitute a serious danger to the patient. The present investigation was planned in order to determine the frequency with which specimens of cerebrospinal fluid, sent to the laboratory for examination are contaminated with water-borne organisms which would be missed by the routine bacteriological methods usually relied on and to discover whether the presence of such organisms in cerebrospinal fluid is always attributable to the technique of lumbar puncture employed. It comprises the bacteriological examination of 223 cerebrospinal fluids and of a number of sterilised waters in current use at several different hospitals. Finally a few cerebrospinal fluids were examined which had been specially collected by techniques designed to avoid any possibility of contamination.

EXAMINATION OF CEREBROSPINAL FLUIDS

Methods.—Cultures were made from all specimens of cerebrospinal fluid received at the laboratory irrespective of the purpose for which they had been submitted. Quantities varying from 4 to 15 drops, according to the amount available, were seeded into duplicate tubes of Witte peptone water one of which was kept at room temperature and the other at 37° C for 7 days. If either tube showed any opalescence or other sign of bacterial growth within this period stained films and dark ground preparations were examined and subcultures made on fresh peptone water digest broth, agar and blood-agar plates. The organisms isolated were investigated sufficiently to place them in one of the groups listed in table II; in many cases definite species identification was simple. No attempt was made to duplicate the tests carried out in the routine department. After sufficient fluid for the peptone-water cultures had been withdrawn specimens were passed on to that department for the examinations required by the clinicians; thus fluids sent in for Wassermann reaction or chemical tests only received no further cultural examination while those submitted for bacteriological diagnosis were cultured on agar and blood-agar plates and the remaining portion of fluid incubated, all at 37° C and for not longer than 48 or 72 hours. It was no part of our intention to obtain the maximum percentage of positive cultures of all types of organisms by the employment of special culture media or improvements on the routine technique.

Results.—The results obtained by prolonged cultivation in peptone water at both room temperature and 37° C are summarised and compared with those yielded by the routine tests in table I. While 154 specimens were examined by both methods an additional 69 were cultured in peptone water only. These latter were sent to the laboratory for Wassermann reaction or chemical tests only and were presumably from patients without signs of bacterial infection; their inclusion therefore weighted the chances of yielding positive cultures against the peptone water (P.W.) group in favour of the routine group. Nevertheless the percentages of C.S.F.s giving growth of organisms in the two groups showed no significant difference—43% in the P.W. group against 37% in the routine group. This was so in spite of the fact that meningococci or pneumococci were isolated by peptone-water cultures from only 8 of the 42 specimens which were shown by routine culture to contain these pathogens. If the organisms that were responsible for disease in the C.S.F. donors are excluded from consideration the value of the P.W. technique is strikingly illustrated, 39.9% of fluids giving positive peptone-water cultures as compared with 9.7% giving positive routine cultures. There are several obvious reasons for this difference. The amount of cerebrospinal fluid inoculated into the peptone-water tubes was usually much greater

TABLE I—ISOLATION OF ORGANISMS FROM CEREBROSPINAL FLUIDS

Cerebrospinal fluids	Peptone water culture	Routine culture at 37° C
	No and %	No and %
Total examined	223*	154
Growth at—		
37° C only	30	—
RT only	15	
RT and 37° C	52	
Total giving growth	97 (43.5)	57 (37)
Organisms isolated—		
Pathogenic	8 (3.6)	42 (27.3)
Contaminant	89 (39.9)	15 (9.7)
Sterile	126 (56.5)	97 (63)
One species only isolated	89 (39.9)	54 (35.1)
More than one	8 (3.6)	3 (1.9)

* These included the 154 specimens also examined by routine culture. RT = Room temperature

than the amount spread over routine plates and P W cultures were incubated for 6–7 days instead of the routine 2–3 days Moreover, it will be seen from table I that 15 specimens of C S F contained bacteria which grew out in culture at room temperature but failed to grow at 37° C It should be added that many more specimens contained organisms which preferred the lower temperature though capable of multiplying to some extent also at 37° C The majority of contaminated C S F s contained only one bacterial species but a few contained two or even three different species

---

* Working with part time grant from Medical Research Council.

[1] Barrie, H. J. *Lancet*, 1941, 1, 242.

TABLE II—TYPES OF ORGANISMS ISOLATED FROM CEREBROSPINAL FLUIDS

Contaminant	PW culture at RT and 37° C No (223) and %	Routine culture at 37° C only No (154) and %
Water organisms—		
Unidentified species	23 } (14 8)	0
Ps fluorescens	10 }	0
Staph albus	33 (14 8)	8 (5 2)
Sarcinæ and *Micrococcus tetragenus*	9 (4)	1
Non hæmolytic streptococci	4	1
Coliform organisms	11 (4 9)	4 (2 6)
Sporing aerobes	3	5
Proteus vulgaris	1	0
Diphtheroids	0	1
Yeast	1	0
Meningococci and pneumococci	8 (3 6)	42 (27 3)
Nil (specimens sterile)	126 (56 5)	97 (63)

PW = peptone water

Table II shows the different types of organism isolated The most striking feature is the frequency with which those organisms considered to be water-borne were isolated by P W culture (14 8%) and the complete failure of routine culture methods to reveal the presence of contaminants of this nature in any single instance The water-borne organisms included *Pseudomonas fluorescens* and unidentified species belonging to that genus and to the groups *Chromobacterium* and *Achromobacterium* Many of them showed some degree of serological relationship by cross-agglutination tests although quite distinct in their morphological and cultural characteristics Three species were by normal human sera to a titre of about 1 in 20, sera tested all gave the same result

Apart from the water organisms the contaminants were *Staphylococcus albus* (derived sumably from the skin of either patient or coliform bacilli and micrococci Somewhat to surprise these species also were isolated from a proportion of fluids by P W culture than by culture

EXAMINATION OF HOSPITAL "STERILE" WATERS

On inquiry at four hospitals in and around we learnt that in each of them cold sterilised water used for rinsing spinal-puncture needles before the operation Different methods of sterilisation were employed, not only in the different hospitals but in different units of the same hospital, technique adopted in each case being traditional some instances the job was carried out in the wards the nursing staff, in others by the hospital laboratory technician in yet others by the dispensary pharmacist In no unit was the destruction of all possible contaminants, including resistant spores, ensured by the method of autoclaving the water at increased pressure Water once treated and labelled "sterile" was considered to be sterile until the bottle was empty, no matter how many withdrawals had been made or what time had elapsed since it had been first put into commission In several cases the time interval between sterilisation and collection of our sample could not be ascertained, 7 days was the longest recorded

Eleven samples were obtained, each being collected with a sterile pipette into a sterile test-tube and transported immediately to our laboratory for culture The technique of peptone-water culture and subsequent investigation was the same as that used for the cerebrospinal fluids The results obtained are summarised table III Six samples were found to be contaminated the other five were apparently sterile though it is possible that some of them would have given growths had a variety of culture media been used Contaminated specimens were obtained from all four hospitals In hospital A, six specimens were taken from different blocks and two of them were found to be contaminated It is significant that in each of these two cases a special note was made at the time of sampling that the bottle was already half empty

TABLE III—ISOLATION OF ORGANISMS FROM HOSPITAL STERILISED WATERS

Specimen	Hospital	Growth	Characteristics of isolated organisms									Water sterilisation methods
			Shape	Gram	Motility	Sugars	Indole	Litmus milk	Pigment	37° C	RT	
1	A Block 1	–										Bottle kept for 3 hr in bath of boiling water Samples taken 3½ hr after sterilisation
2	A Block 3	+	CB	–	+	–	–	NC	–	+	++	Winchester in bath of boiling water Most of contents already used at time of sampling 7 days after sterilisation
3	A Block 4	–										Bottle kept for 1¼ hr in bath of boiling water Samples taken 2 days after sterilisation
4	A Block 9	+	CB	–	+	–	–	NC	Yellow	–	+	Winchester in bath of boiling water Half contents already used at time of sampling 2 days after sterilisation
5	A Block 9	–										Winchester in bath of boiling water Unused before sampling 5 hrs after sterilisation
6	A Cas dept	–										Water filtered then heated in steriliser to 200° C Sample taken direct from steriliser
7	B Ward 1	+	CB R	– –	+ –	– –	– –	NC Alk	– Orange	+ ++	++ +	Tap water boiled in kettle for 5 min, then poured into a sterilised bottle Bottle about half full when sampled
8	B Ward 2	+	CB	–	+	–	–	NC	–	+	++	Ditto
9	C	+	R	–	–	–	–	Alk	–	++	+	Autoclaved Winchester filled direct from a Stokes still Bottle almost empty at time of sampling
10	D	–										Jug sterilised in a boiler for 20 min then filled from kettle and covered with jaconette Full at time of sampling
11	D	+	R	–	+	–	–	Alk	–	+	+	Glass stoppered pot sterilised in boiler for 20 min and filled from kettle Half contents used at time of sampling 24 hr after sterilisation

CB = cocco bacillary R = rod shaped, NC = no change, Alk = production of alkali

TABLE IV—BACTERIOLOGICAL EXAMINATION OF SPECIALLY COLLECTED CEREBROSPINAL FLUIDS

[illegible]	Hospital	Result of culture	Technique of C S F collection
1	A	Sterile	Needle and syringe autoclaved in plugged test tube Rubber gloves and mask worn by operator Patient's skin washed with soap and water swabbed with spirit and painted with 10% aqueous iodine Local anæsthetic (2% procaine) injected with autoclaved needle and syringe
2			
3		Growth +, diphtheroid	
4	"	Sterile	
5	"	"	
6	"	"	
7	B	Growth +, 2 different organisms identical with species isolated from sterilised water (no 7, table III)	Routine technique Needle rinsed in sterilised water (no 7, table III) before use
[illegible]	C	Growth + organism identical with that isolated from sterilised water (no 9, table III)	Needle kept in spirit, rinsed in sterilised water (no 9 table III) before use
9		Sterile	Lumbar puncture performed in operating theatre with full aseptic precautions Local anæsthetic given Needles and syringes sterilised by boiling at time of operation

11	"		
12	"		

All the organisms isolated were similar to some of those obtained from routine cerebrospinal fluids They were all gram-negative bacilli or cocco-bacilli indole-negative and fermenting no sugars, but they showed differences in respect of morphology motility production of alkali in litmus milk and formation of pigment Direct proof of the transference of such bacteria from water to C S F at the time of spinal puncture is afforded by the results from waters nos 7 and 9 (table III) and C S F s nos 7 and 8 (table IV) These C S F s were collected through needles which had been rinsed in the respective waters and identical organisms were isolated from the corresponding specimens In the case of water 7 and C S F 7 each specimen contained the same two quite different species

EXAMINATION OF SPECIALLY COLLECTED CEREBROSPINAL FLUIDS

Of the 89 routine C S F specimens contaminated with non pathogenic bacteria, rather more than a third contained water-borne organisms and rather less than two-thirds organisms which were mostly derived from skin and clothing (tables I and II) It is clear therefore that the technique of C S F collection in general and hospital practice is unsatisfactory quite apart from the use of so-called sterile water A small number of specially collected specimens was examined to convince ourselves that sterile fluids can be obtained provided just a little extra trouble is taken They were supplied from hospitals which had previously sent full quotas of contaminated C S F s to the laboratory for bacteriological diagnosis The special precautions adopted and the results of peptone-water culture are given in table IV Two of the specimens (nos 7 and 8) have already been discussed they were collected by the old technique and examined in parallel with the waters (nos 7 and 9 table III) used to rinse the puncture needles From them the water contaminants were readily isolated Apart from these one fluid only out of ten gave bacterial growth, the organism being a diphtheroid probably of skin derivation The use of boiled or autoclaved needles and syringes led therefore, as was expected, to the complete elimination of water contaminants and the application of reasonable standards of cleanliness prevented other contamination except in one instance

COMMENT

It is clear that spinal puncture is performed in many hospitals and presumably in private practice also, in light-hearted fashion without the ordinary measures of asepsis which patients and laboratory workers have the right to expect It is probable that this bad practice leads, as a rule, to nothing more serious than the contamination of specimens withdrawn for laboratory tests but the possibility of operative infection of the meninges is obvious This danger is of course, greatly increased when material such as anæsthetic fluid is injected into the spinal canal

The practice of using previously sterilised or filtered water for rinsing syringes and needles cannot be too strongly condemned, for it is entirely unnecessary and the contamination of stock water bottles appears to be the rule rather than the exception The contaminants are mostly species which are usually considered non-pathogenic, but the outbreak of meningitis reported by Barrie strongly suggests that potential pathogens may sometimes be present. The possibility of the transference of infective viruses like the virus of lymphocytic choriomeningitis in filtered water though remote also merits consideration The adoption of simple boiling, or better still either oven sterilisation or autoclaving in plugged test-tubes for the sterilisation of needles and syringes would at once reduce the number of contaminations by over a third and eliminate one of the chief sources of potential infection

SUMMARY

Of 223 unselected specimens of cerebrospinal fluid 89, or 39 9%, were shown to be contaminated with non-pathogenic organisms by cultivation in simple peptone water at both room temperature and 37° C Bacteriological examinations of 154 of the same specimens by routine methods revealed contaminants in only 15 or 9 7%

The peptone-water technique was superior to routine culture for the isolation of almost all types of non-pathogenic bacteria and was essential for the demonstration of water organisms which accounted for 37% of the contaminants

Many sterilised waters used in different hospitals for rinsing spinal puncture needles and syringes were found to be contaminated.

Direct evidence was obtained that bacteria may be transferred from such water to cerebrospinal fluid at the time of operation

Of 10 cerebrospinal fluids collected with reasonable aseptic precautions 9 were bacteriologically sterile and 1 was contaminated with a diphtheroid

We are indebted to Mr J Hardman, Dr K. J G Milne and Dr H J Barrie for their help in the collection of material

TREATMENT OF AIR-RAID CASUALTIES [*]

JOHN A SHEPHERD M D ST AND F R C S E
SURGEON LIEUT COMMANDER R N V R

THE publication of every experience in the reception and treatment of air-raid casualties is of great importance It is by the pooling and collection of all results and even impressions, that many gaps in our knowledge will be filled At a Service hospital there has been a special opportunity for testing planned resuscitation and operative schemes

RECEPTION AND RESUSCITATION

It was found best to admit patients into resuscitation wards irrespective of their condition and then filter them through into the operating-theatres or other wards Patients who were obviously severely wounded were placed in beds on one side of the ward so that they could be examined first When the first resuscitation ward was full admission was diverted to the second The patients were placed between warmed blankets and the clothing completely taken off in every case It was found that delay in taking off clothing results in important injuries being missed, and the thick often damp clothing cannot be penetrated adequately even by heat from shock cages Only one examining team was utilised to prevent overlap and confusion and they moved round the ward methodically examining the cases in strict rotation A list for operation was made at an early stage and this enabled the operating-tables to be fed within an hour of receipt than the amount spread over routine plates and P W cultures were incubated for 6–7 days instead of the routine 2–3 days Moreover, it will be seen from table I that 15 specimens of C S F contained bacteria which grew out in culture at room temperature but failed to grow at 37° C It should be added that many more specimens contained organisms which preferred the lower temperature though capable of multiplying to some extent also at 37° C The majority of contaminated C S F s contained only one bacterial species but a few contained two or even three different species

---

[*] A more detailed account of these casualties appeared in the *Journal of the Royal Naval Medical Service* for October 1941 p 330

TABLE II—TYPES OF ORGANISMS ISOLATED FROM CEREBROSPINAL FLUIDS

Contaminant	PW culture at RT and 37° C	Routine culture at 37° C only
	No (223) and %	No (154) and %
Water organisms—		
Unidentified species	23 } (14 8)	0
Ps fluorescens	10 }	0
Staph albus	33 (14 8)	8 (5 2)
Sarcinæ and *Micrococcus tetragenus*	9 (4)	1
Non hæmolytic streptococci	4	1
Coliform organisms	11 (4 9)	4 (2 6)
Sporing aerobes	3	3
Proteus vulgaris	1	0
Diphtheroids	0	1
Yeast	1	0
Meningococci and pneumococci	8 (3 6)	42 (27 3)
Nil (specimens sterile)	126 (56 5)	97 (63)

PW = peptone water

Table II shows the different types of organism isolated The most striking feature is the frequency with which those organisms considered to be water-borne were isolated by P W culture (14 8%) and the complete failure of routine culture methods to reveal the presence of contaminants of this nature in any single instance The water-borne organisms included *Pseudomonas fluorescens* and unidentified species belonging to that genus and to the groups *Chromobacterium* and *Achromobacterium* Many of them showed some degree of serological relationship by cross-agglutination tests although quite distinct in their morphological and cultural characteristics Three species were agglutinat by normal human sera to a titre of about 1 in 20, of sera tested all gave the same result

Apart from the water organisms the common contaminants were *Staphylococcus albus* (derived presumably from the skin of either patient or doctor coliform bacilli and micrococci Somewhat to our surprise these species also were isolated from a higher proportion of fluids by P W culture than by routine culture

EXAMINATION OF HOSPITAL " STERILE " WATERS

On inquiry at four hospitals in and around Sheffiel we learnt that in each of them cold sterilised water wa used for rinsing spinal-puncture needles immediatel before the operation Different methods of wate sterilisation were employed, not only in the differen hospitals but in different units of the same hospital, th technique adopted in each case being traditional I some instances the job was carried out in the wards b the nursing staff, in others by the hospital laborator technician in yet others by the dispensary pharmacist In no unit was the destruction of all possible contaminants, including resistant spores, ensured by the metho of autoclaving the water at increased pressure Wate once treated and labelled "sterile" was considered to b sterile until the bottle was empty, no matter how man withdrawals had been made or what time had elapsed since it had been first put into commission In several cases the time interval between sterilisation and collection of our sample could not be ascertained, 7 days was the longest recorded

Eleven samples were obtained, each being collected with a sterile pipette into a sterile test-tube and transported immediately to our laboratory for culture The technique of peptone-water culture and subsequent investigation was the same as that used for the cerebrospinal fluids The results obtained are summarised in table III Six samples were found to be contaminated, the other five were apparently sterile though it is possible that some of them would have given growths had a variety of culture media been used Contaminated specimens were obtained from all four hospitals In hospital A, six specimens were taken from different blocks and two of them were found to be contaminated It is significant that in each of these two cases a special note was made at the time of sampling that the bottle was already half empty

TABLE III—ISOLATION OF ORGANISMS FROM HOSPITAL STERILISED WATERS

Specimen	Hospital	Growth	Characteristics of isolated organisms									Water sterilisation methods
			Shape	Gram	Motility	Sugars	Indole	Litmus milk	Pigment	37° C	RT	
1	A Block 1	–										Bottle kept for 3 hr in bath of boiling water Samples taken 3½ hr after sterilisation
2	A Block 3	+	CB	–	+	–	–	NC	–	+	+ +	Winchester in bath of boiling water Most of contents already used at time of sampling 7 days after sterilisation
3	A Block 4	–										Bottle kept for 1½ hr in bath of boiling water Samples taken 2 days after sterilisation
4	A Block 9	+	CB	–	+	–	–	NC	Yellow	–	+	Winchester in bath of boiling water Half contents already used at time of sampling 2 days after sterilisation
5	A Block 9	–										Winchester in bath of boiling water Unused before samplin 5 hrs after sterilisation
6	A Cas dept	–										Water filtered then heated in steriliser to 200° C Sample taken direct from steriliser
7	B Ward 1	+	CB R	– –	+ –	– –	– –	NC Alk	– Orange	+ + +	+ + +	Tap water boiled in kettle for 5 min, then poured into a sterilised bottle Bottle about half full when sampled
8	B Ward 2	+	CB	–	+	–	–	NC	–	+	+ +	Ditto
9	C	+	R	–	–	–	–	Alk	–	+ +	+	Autoclaved Winchester filled direct from a Stokes still Bottle almost empty at time of sampling
10	D	–										Jug sterilised in a boiler for 20 min then filled from kettle and covered with jaconette Full at time of sampling
11	D	+	R	–	+	–	–	Alk	–	+	+	Glass stoppered pot sterilised in boiler for 20 min and filled from kettle Half contents used at time of sampling 24 hr after sterilisation

CB = cocco bacillary, R = rod shaped, NC = no change, Alk = production of alkali which an acute Volkmann's ischæmic contracture, with all the typical signs developed 12 hours later The brachial artery was explored and found to be contracted to a diameter of about ⅙ in in its entire extent An arterial sympathectomy and excision of an arterial segment failed to relieve the arterial spasm Both legs had to be amputated for crush injuries in this case and the patient collapsed and died shortly after the operation

Simple fractures —These 34 cases (14% of the total) illustrate the great importance of a specialised knowledge of the treatment of fractures in air-raid cases The upper and lower limbs received an equal proportion of injuries A patient with a dislocation of both hip-joints and multiple pelvic fractures was admitted with severe shock (systolic blood-pressure unrecordable) after a heavy mass of concrete had fallen on his sacral region while he was bending down After resuscitation with 3 pints of plasma and early skeletal traction through the tibial crest he recovered

Burns —With certain exceptions burns were treated successfully with tannic acid 5% and silver nitrate 10% This produces a rapid coagulum, an important point when many cases have to be treated Certain areas were never tanned—the eyelids, lips, genitalia ears and fingers Burns of the fingers were treated on light plaster splints in the position of function with Ambrine wax applied on strips of gauze This method has given excellent healing and good functional results where the initial injury was not too severe The bad results attributed to tanning methods are more likely due to the initial damage by the burn The ambrine wax method is, however, much more comfortable, and indeed has been applied to other areas

Eye injuries —There were only 4 cases of eye injury and in 2 of these the damage was due to metallic splinters, for which the affected eyes had to be removed Multiple fine corneal foreign bodies and corneal abrasions accounted for the other 2 cases

Minor and unclassified injuries —There were 71 cases of minor injury (29% of the total), most of them having minor lacerations sprains or slight shock Many required X-ray examination In the unclassified list are included 16 patients (7% of the total), several of whom had multiple injuries or had been buried for some time There were 2 who developed all the signs of a crush-syndrome lesion of the lower limb and recovered, and 4 cases of blast lung, 2 of which were diagnosed by X ray A stout bronchitic man, with no other lesion except a fractured radius, died after a hæmoptysis which suggested a blast lesion Included in this unclassified list are 3 patients with multiple bone injuries to the trunk who died shortly after admission

There were 2 cases of spinal-canal injury Both were explored and the missiles removed The one recovered fully but in the other there was damage to the cord with paraplegia

COMMENT

Antitetanic serum was given as a routine in all wounds including burns; no case of tetanus occurred Patients with muscle damage were given 8000 units of anti gas gangrene serum No definite conclusions have been reached on the practical value of chemotherapy either generally or locally During actual convalescence, after the study of a number of blood-counts in a series of cases, it was found that fresh blood-transfusion is of great value in the post-operative period The importance of close observation of urinary output and renal efficiency must be particularly stressed to the nursing staff especially in amputation cases and crush injuries Post mortem examinations wherever possible are desirable, but owing to administrative difficulties in obtaining the necessary permission much material is being lost

SUMMARY

In a series of 245 air-raid casualties the mortality was 10% The use of intensive resuscitation measures was shown to be fully justified in severe cases of injury, and a planned system of resuscitation and treatment is advocated

VITAMIN A AND DARK-ADAPTATION
EFFECT OF ALCOHOL, BENZEDRINE AND VITAMIN C

SIMON YUDKIN, M B LOND, M R C P
FLIGHT LIEUTENANT, R A F V R
(*Department of Chemical Pathology, University College Hospital Medical School*)

THE relation between vitamin A and dark-adaptation depends on three known facts First, vitamin A is a constituent part of the photosensitive pigment of the rods and possibly also of the cones (Wald 1935, Hecht 1940) Secondly most cases of night-blindness are cured with vitamin A (Hecht and Mandelbaum 1939, Lewis and Haig 1940, Edmund and Clemmesen 1936) Thirdly, night-blindness can be produced by feeding on a diet deficient in vitamin A (Wald et al 1938, Booher et al 1939) All relevant investigations are based on one or more of these facts Many of the workers who have argued as to their truth have used inaccurate methods of testing dark-adaptation, either of the "recovery-time" type or a similar method (see Dow and Steven 1941 for detailed criticism of these methods) The present study was undertaken in the hope of throwing further light on some aspects of the subject

Methods —Dark adaptation was measured by the apparatus and method described by Yudkin (1941a) The initial part of the curve was obtained by using no neutral screen for the first few minutes The vitamin A content of the blood was estimated by the method described earlier (Yudkin 1941b)

The significance of changes in the dark-adaptation curve and the blood vitamin A following any treatment must be considered in the light of their normal variation

The final rod threshold tested as described on any one subject varied by about 0 2 log unit from day to day, by about 0 1 log unit in a shorter period of a few hours and hardly at all during an hour The cone threshold, owing partly to the absence of a "fixation spot" in the instrument, varied more than this—i e, about 0 3 log unit from day to day and about 0 2 log unit over a short period The rod-cone transition time varied up to about 2 min from day to day but less than 1 min on any one day These variations are not apparently related to fatigue or practice (personal observation) but may be related to changes in the blood-sugar (McFarland and Forbes 1940) Only differences greater than those described can be considered significant in any one case If, however, there are significant changes in several subjects after a particular treatment this increases the importance of smaller changes in other subjects if they are all in the same direction Also if several control tests have been made with any one individual, any change from these may be significant even if less than the normal range of variation It is worth noting that although the final rod threshold varies in any individual by 0 2 log unit, the total variation among normal people was found to be 0 3 log unit (for definition of "normal" see Yudkin 1941a) It is possible, therefore, for the values for the final rod threshold of an individual to lie in the upper part of the normal (total) range of variation and yet show a significant lowering after vitamin-A therapy

The resting level of vitamin A in the blood varies by about ± 5% over periods of days or weeks, and it is not affected by food unless this is very rich in vitamin A These changes may be due to different degrees of adrenal cortical (Malmejac, Chevallier and Choron 1935) or medullary (Thiele and Guzinski 1940) stimulation

These variations in blood vitamin A and dark-adaptation are quite independent and may be in opposite directions, so that a lower level of blood vitamin A may be associated with a better dark-adaptation curve and vice versa

EFFECT OF VITAMIN A ON SUBJECTS WITH POOR DARK-ADAPTATION

Effect of a single dose —Single doses of about 100,000 I U of vitamin-A alcohol in gelatin capsules containing 25 000 I U each were given on an empty stomach The effect on the dark-adaptation curve was followed during the next 24–36 hours or longer if the effect was prolonged, food being taken after 3 hours The dark-adaptation was measured at 1, 4, 7, 10 and 24 of the casualties. This operating list was of course subject to frequent revision, but unless it was begun early it was inevitable that it would prove difficult to deal with patients in the "safe period." We were impressed with the necessity for examining the whole body from top to toe and it was astonishing how small but serious wounds could otherwise be missed. The best and simplest method of recording injuries was under anatomical regional headings such as head, arms, chest, abdomen, legs and spine.

The average degree of shock encountered in air-raid casualties far exceeded that seen in the casualties of civil life. The nature of the injuries and the state of the blood-pressure were the best signs of its gravity. Early rapid resuscitative measures were strongly advisable. Severe shock had to be tackled whole-heartedly. Besides heat, elevation of the foot of the bed on 18 in blocks, and intravenous therapy with blood, plasma or reconstituted serum in large doses were necessary. A cannula was always inserted into a vein in cases requiring intensive anti-shock treatment over a long period.

Seriously shocked cases must be given plasma in quantity and given it quickly. It should be possible to run in two pints of plasma in 20 minutes and further quantities up to six pints at rather slower rates as the patient's condition improves. The blood-pressure is usually the best guide to the success or otherwise of plasma- or blood-transfusions. If the systolic pressure does not rise with three pints given quickly it is unlikely that the patient will recover. Patients have been seen with systolic pressures below 50 mm Hg and have improved at the rate of 10 mm Hg for each pint of plasma or blood given. It is useful to maintain a sphygmomanometer cuff on the patient's arm throughout treatment and easy to train the ward staff to take the systolic pressure accurately. In certain cases admitted early after injury the blood-pressure was either maintained or raised for a variable period. In such cases the type and degree of injury led one to suspect that a fall was imminent and this could be prevented if plasma was given to compensate for the fall in circulating blood-volume. Oxygen therapy with the B L B mask was frequently used and with obvious immediate improvement in colour, pulse, and depth of respirations. If the patient did not tolerate the mask it usually meant that he did not require oxygen. Many patients asked for it to be reapplied if it was removed. Instruction in the use of the mask had been part of the regular training of the ward staff. Among other adjuncts to the treatment of wound shock are the intelligent temporary splinting of fractures especially those of the femur, the utilisation of early skeletal traction under local anæsthesia in the ward, and the local blocking of injured limbs with 1% procaine.

Resuscitation measures are only temporary in their effect in most of these cases. Where operation is delayed a patient may reach a peak of improvement and then relapse despite all further resuscitative measures. Patients must if possible be operated on when on the up grade. Approximately 70% of the cases given intense preliminary resuscitation survived operation.

CASES ANALYSED

	Total	Died
Head injuries	35	4
Chest injuries	3	2
Abdominal injuries	8	8
Compound fractures	22	5
Simple fractures	34	0
Bomb splinter wounds of soft tissue	37	0
Laceration of soft tissues	7	0
Burns	8	0
Eye injuries	4	1
Minor injuries	71	0
Unclassified	16	4
Total	245	24

A consecutive series of 245 air-raid casualties aged 20–50 years, most of whom had previously been healthy, are analysed here. Nearly all were admitted within 1–3 hours of the injuries and all patients admitted alive into the reception wards are included. The death-rates have been calculated up to a period of a week from t day of injury. The total fatality-rate was 10%.

Head injuries include scalp lacerations, concussion a closed or compound fractures of the skull. Altogeth there were 35 cases (14% of all cases), 9 being sca injuries and 12 suffering from concussion. The fatalit rate was 11%. The diagnosis of these head injuries w simple in some cases but in many with other multip severe injuries the degree of shock made it difficult assess the cerebral lesion. Accurate neurological e amination was often impossible in the early stages examination. It was made the rule to take every sca laceration to the theatre for thorough exploration a toilet of the wound. Most of the compound injuri of the skull were due to falling debris, and it should more widely realised that steel helmets are as usef indoors as out. There were 8 cases of compou depressed fracture of the skull and 6 were fit for oper tion, all of which recovered.

Abdominal injuries.—These made a depressing serie there were 8 cases (3% of the total), of which only reached the operating-table and all subsequently died 3 of these had hopeless lacerations of the abdomin contents and died immediately or soon after abdomin closure. In one case, where the liver had been injure by a bomb splinter the patient died a few days afte operation from a pneumonic infection and a sma subhepatic bile-stained abscess.

Chest injuries.—Of the 3 patients admitted with che injuries 2 were quite inoperable and died shortly afte admission. Both these patients had multiple bomb splinter penetrating wounds with other compound injuries. The one patient who was successfully operate on received a small bomb-splinter wound in his lef lower chest and the fragment actually lodged in the righ side of the chest. The only operative interference wa excision of the entry wound. He subsequently develope a hæmothorax on the right side which was treated b aspiration.

Compound limb injuries and soft-tissue lacerations.—These 65 cases made up 26% of the total. The value o the closed-plaster method was confirmed. Among it other advantages it enabled amputation cases and other to be rapidly transferred to base hospitals. This wa found to be particularly important from the patients point of view, for with the prospects of further nightly raids they were apt to be nervous or sleepless. The wounds were widely and thoroughly excised, sutures were avoided wherever possible and the wounds packed with Vaseline gauze. By adopting the pattern technique for plastering the limbs much time was saved. A hip spica could be applied in 8 minutes. All cases were examined radiologically before operation; in this way the presence of metal fragments was confirmed and their type and localisation noted, so that the scope of the operation required for excision of the track could be assessed. The small penetrating wounds of fascia with gross damage of underlying muscle were a real danger unless adequately treated. Complete plaster immobilisation was an essential in soft-tissue limb injuries as in compound fractures.

There were 36 cases (14% of all cases) of bomb splinter wounds of soft tissues, 15 of them involving either the buttock or thigh. The high incidence of such wounds is presumably due to the prominence of the buttocks when people throw themselves down for protection. There were no deaths in the soft-tissue injuries, which included 2 cases of severe local gas gangrene infections; these recovered after wide local drainage serum and early immobilisation in closed plaster. There were an additional 7 cases of lacerations due to glass. It was found safe to employ primary suture for these inside 12 hours.

There were 22 compound fractures of the limbs and 8 of these required amputations; 2 patients requiring upper-limb amputation recovered, but 4 out of the 6 patients whose lower limbs were amputated (2 double amputations) died. Subsequent renal failure, with a probable associated cerebral lesion, was responsible for 2 of these deaths. Of the remaining 14 compound fractures, including 4 of the femur, all recovered except one patient with aortic incompetence who collapsed and died suddenly 24 hours after the injury. Of special interest was a case of compound injury to the humerus within the normal range dark-adaptation and blood vitamin A may vary in opposite directions also shows that other factors must affect dark-adaptation Moreover congenital and hereditary night-blindness and certain diseases of the retina affect the dark-adaptation independently of vitamin A The only proof that any subject has poor dark-adaptation because of deficiency of vitamin A is the improvement of the dark-adaptation curve with vitamin-A therapy It is essential to use a stringent test such as that described if very deficient subjects are not to be missed, because of the transient effect of small doses on such subjects In practice, by far the commonest cause of a high threshold is deficiency of vitamin A and surveys of threshold values in a population show almost entirely differences in the state of nutrition in respect of this vitamin

Even when it is known however, that vitamin A can cure a case it is not known what part of the cycle of vitamin A metabolism is at fault Any of the stages between the diet and the conversion to the retinal pigment may be affected and any of these conditions might be cured by large doses of vitamin A Investigations into the different parts of this cycle are very sparse (see Patek and Haig 1939 Chevallier and Choron 1938, Thiele and Klodwig 1939 Lindquist 1938 May et al 1940)

The relation between the blood vitamin A and the degree of night-blindness is also complicated It is clear that since vitamin A can improve hemeralopia there must be some relationship between the vitamin A available to the retina and the curve of dark-adaptation From the results described here it is certain that there is no standard level of blood vitamin A which could be used as a test for deficiency instead of the "threshold lability" test On the other hand in any individual there does appear to be a critical level of blood vitamin A below which the final rod threshold is abnormal Below this level the lower the blood vitamin A the higher the rod threshold Raising the blood vitamin A above this level however does not improve the final rod threshold

It is not known whether the level of blood vitamin A bears any relationship to the reserves of the body, as found in the liver, or why there should be different normal levels of blood vitamin A in different people

The mechanism of the action of alcohol and benzedrine on dark-adaptation is obscure nor is it necessarily the same in both The effects are not related to the amount of subjective effect produced and in the case of benzedrine the general effects are maximal after the effect on dark-adaptation has worn off They are also not associated with changes in the blood vitamin A, in fact, they may produce an improvement beyond that possible with vitamin A and threshold values may be found considerably lower than those met with in even the best normal individuals The use of these drugs, and especially of alcohol, for improving dark-adaptation must be considered in the light of their other, more obvious, effects

SUMMARY

In a subject with night-blindness due to vitamin-A deficiency a single dose of the vitamin may produce no improvement, an improvement lasting a few hours, or one lasting several days or weeks

A severely deficient subject given repeated doses of vitamin A will show no response or a transient response at first and a more prolonged effect after further dosing

The dose of vitamin A required to produce prolonged improvement is usually between 300 000 and 2,000,000 I U This dose is not related to the initial degree of night blindness

In testing whether a case of night-blindness is due to deficiency of vitamin A possible transient responses must be borne in mind It is necessary to ensure (*a*) that the dose is adequate and (*b*) that the test is performed at a time when improvement is likely

There is no standard level of blood vitamin A which would indicate whether a subject is deficient in vitamin A or not

In any single individual there is a critical level of blood vitamin A Below this level, the lower the blood vitamin A the higher the final rod threshold

Alcohol and benzedrine both produce transient improvement in dark-adaptation without any corresponding rise in blood vitamin A The resulting improvement may be beyond that possible with vitamin A

Vitamin C has not been found to improve any subject tested even if originally deficient in this vitamin

I should like to thank Prof C R Harington for his encouragement and for the laboratory and other facilities, and Dr A G Spencer for his coöperation in some of the preliminary investigations

I am indebted to British Drug Houses Limited for generous supplies of vitamin-A alcohol and esters

SIGNIFICANCE OF INTELLIGENCE IN SKIN CASES

Geoffrey A Hodgson, D M OXFD
CAPTAIN, R A M C (T), GRADED DERMATOLOGIST

In a previous paper (Hodgson 1941) I showed that subnormal intelligence was very common among Army patients suffering from scabies During recent months the intelligence of 1002 patients attending a military dermatological clinic was tested by the R E C I matrices (Penrose and Raven 1936, Raven 1939), and allotted by a method previously described to one of the following grades (*a*) very inferior intelligence, (*b*) below average intelligence (*c*) average intelligence, (*d*) above-average intelligence

Every patient who attended the clinic during the period suffering from a disease shown in the first column of table I was tested in this way This table also shows for each disease the number of patients examined and the results of the intelligence test

For the purposes of comparison these diseases can be classified into three groups skin diseases, infestations;

TABLE I—GROSS FIGURES FOR ALL DISEASES

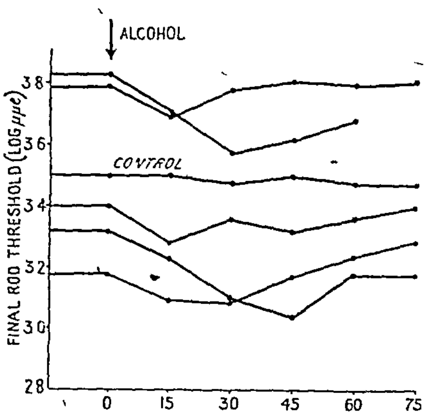

FIG 5—Final rod threshold in 5 subjects given 20 ml alcohol and in a control without alcohol

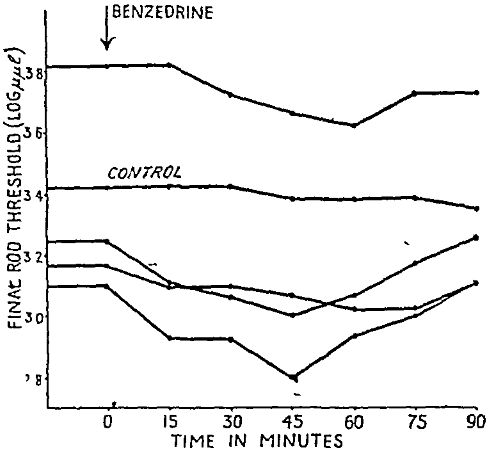

FIG 6—Final rod threshold in 4 subjects given 10 mg of benzedrine and in a control without benzedrine

more accurately than this, for the reaction did not always occur at a definite fixed time. The effect on blood vitamin A was determined by estimating a sample taken before and at the probable time of maximum effect after the substance was given.

Alcohol.—The dose of alcohol used was 20 ml in the form of 100 ml sherry. Preliminary testing showed that there was no difference in the reaction whether pure diluted alcohol or sherry was used, so that the more pleasant vehicle was given. The effect of the final rod threshold in five cases is shown in fig 5. It is seen that there is a definite improvement in each case even when the original threshold was very low. The change begins almost immediately and continues for about an hour.

The effect on the rest of the curve is shown in table II. The alcohol was given half an hour before the test was started. It is seen that the part of the curve showing most change was not always the same, the divergence probably depending on differences in the time of maximum effect of the alcohol. Although the changes were not always significant, even the smaller improvements were in the same direction and there was no curve which was worse after the alcohol. Three cases (12, 13, 14a) showed no effect in any part of the curve by this test. In one of these (14a) the alcohol was given on another occasion immediately before the test, and a significant change occurred in the first part of the curve but passed off in about 20 min (14b). The other two cases may have shown no response for a similar reason.

There was no significant change in the blood vitamin A in any case. The results varied in both directions and always within normal limits. To emphasise this point—that the improvement does not depend on a concomitant rise in blood vitamin A—two subjects whose normal variations were in the upper part of the normal distribution curve were given 120,000 I U of vitamin A and tested at intervals thereafter. There was no definite change in any part of the curves, though the blood vitamin A rose to more than 500 I U per 100 ml serum. These same two subjects showed a significant effect with alcohol.

Benzedrine (amphetamine sulphate).—The dose used was 5 or 10 mg on an empty stomach, given half an hour before the test. The effect on the final rod threshold is shown in fig 6, and the rest of the curve in table III. Again the parts of the curve most affected varied in different subjects. Only one of the subjects tested (9) showed no effect in any part of the curve. The blood vitamin A, as with alcohol, showed no significant change. The two subjects who showed no improvement with vitamin A but reacted to alcohol also responded to benzedrine. The effect seemed to be wearing off after an hour and a half. The mental effect was greatest several hours later but two subjects tested at this period showed no change in dark-adaptation.

VITAMIN C AND DARK-ADAPTATION

It has been said (Stewart 1941, Kimble and Gordon 1939) that vitamin C may produce an improvement in dark-adaptation. According to Stewart, who gave 150 mg daily for 7 or 14 days, the effect was sometimes seen in subjects resistant to vitamin A therapy, while in other subjects it was superimposed on a partial improvement produced by vitamin A. It is not stated whether these subjects were deficient in vitamin C as shown, for example, by "saturation" tests. In the present work no such effect of vitamin C has been observed in any subject. Six subjects with poor dark adaptation were given 500 mg vitamin C daily for 10 days. In none of these was any improvement noted whereas all subsequently became normal with vitamin A. Five subjects with normal curves in the upper part of the normal variability curve also showed no improvement with this dose.

In another subject with severe night-blindness the excretion of vitamin C was followed during dosing. He was found to be decidedly "unsaturated," requiring 8 days' dosing (total 4000 mg vitamin C) before the urinary excretion rose significantly. At the end of this time the dark-adaptation curve had not altered. Further dosing for 14 days with 100 mg daily was also without effect. The subject was then given a total of 900,000 I U of vitamin A over a period of 14 days, at the end of which his dark-adaptation curve was normal. Further investigation of the effect of vitamin C is needed.

DISCUSSION

It is not to be expected that vitamin A is the only factor affecting dark-adaptation. In a process so complicated, and involving not only the photochemical changes in the retina but the transmission of nerve impulses and the interpretation of these in the cortex, it is obvious that any link in the chain may be affected. Thus lack of oxygen and hypoglycæmia (McFarland and Forbes 1940) as well as benzedrine and alcohol all produce a change in dark-adaptation, the latter improvement, the former deterioration. As we have seen, benzedrine and alcohol produce their effect without any corresponding change in the vitamin A of the blood. The fact that,

symptoms of anæmia breathlessness, palpitation, weakness or giddiness Other common complaints are of swelling of the feet and cough Sometimes there is no complaint of ill health, and at other times the complaint may be of fever, dysentery or the passage of scanty urine The patients are usually well nourished The severe anæmia is characteristically associated with a slight blurring of the features, due to œdema of the face Frank œdema of the feet is common, and this may extend up the abdominal wall There may be a faintly icteric tinge of the conjunctiva, but this is usually associated with concurrent malaria The tongue may be sore, or moist and white and indented by the teeth Sore mouth is not more common in these cases of macrocytic anæmia than it is in the pregnant population as a whole The temperature is usually raised, pyrexia was present in 82 of the cases considered here

There is considerable breathlessness on exertion, a rapid pulse and soft blowing systolic murmurs over the præcordia Œdema was noted in 38 of the 100 cases The respiration-rate is raised in severe cases, and a constant, loose, exhausting cough may be present, accompanied by moist râles in the chest, cough was present in 24 cases of the series Enteritis may be severe and misleading, but clears up as the general condition improves The liver and spleen may be enlarged, splenic enlargement was recorded in 11 cases No sign of involvement of the nervous system was observed

Fæces and urine—The fæces were examined in 85 cases Ascaris ova were found in 17, hookworm ova in 16, *Entamœba histolytica* in 2, trichuris ova in 2 and strongyloides larvæ in 2, *E coli* was present in 7 cases and flagellates in 15 Flagellates are as a rule seen in patients who are debilitated, but there seems little reason to consider them as the cause of the enteritis which is so often present in macrocytic anæmia Albumin, pus organisms and even casts may be present in the urine Infection may have some rôle in causation, but the urine clears as the general health improves Albuminuria was present in 54 cases in the series, and micro-organisms were found in 9 of the 25 cases in which the urine was examined bacteriologically Schistosome ova were present in 2 cases

Blood picture—There is a considerable reduction in the number of red cells When the case is first seen the count is commonly about a million per c mm In several cases the count was below this figure, first blood counts done in 106 pregnancies in the 100 women in the series gave the following results

Red cells (millions)	Cases	Red cells (millions)	Cases
0 4–0 7	2	1 5–2	28
0 7–0 9	12	2–2 35	12
0 9–1 2	27	No record	3
1 2–1 5	22		

In many of these the patient recovered The colour index was over 1 in 78 cases and between 1 and 0 8 in 28 Blood films were examined on 294 occasions red cells with a diameter of over 7 5 μ were observed in 78 (26%), polychromasia in 10 (1%), cells deficient in hæmoglobin in 79 (27%), poikilocytosis in 1 (0 3%), anisocytosis was usual and in most cases macrocytes were present, normoblasts and megaloblasts can usually be found and may be numerous In one case there were 9000 white cells per c mm, with Hb 22%, 900,000 red cells per c mm and 7 normoblasts and 7 megaloblasts per 100 white cells The film in macrocytic anæmia differs from that of true pernicious anæmia in the rareness of poikilocytosis Sickling of the red cells was found in 2 of 9 cases examined for this condition Since the rate for pregnant women as a whole is 13% (Medical Research Institute, Accra), this result appears to correspond with the average The leucocytes are seldom increased, and the differential count showed no significant variation from the normal The inversion in the proportion of polymorphs and lymphocytes mentioned in the literature was observed only in one fatal case Primitive white cells were occasionally observed

The van den Bergh reaction was carried out in only 3 cases The direct reaction was negative in all 3 and the indirect positive, which conforms with the general findings in this disease

COURSE

Without treatment the condition progresses rapidly—in a few days the patient may become comatose and die On the other hand, many cases tend to be cut short by the onset of premature labour The woman may die during labour or in the first day or two of the puerperium, but if she survives this period recovery often sets in and may be as rapid as the progress of the illness in the first place In most cases labour is premature, rapid and singularly bloodless The uterine muscle does not seem to be weakened, and provided the cardiac muscle does not fail birth is swift The infant-mortality and stillbirth rates are high The puerperium tends to be febrile and sepsis added to the anæmia seriously affects the chances of survival

The history of cases treated in hospital contrasts with that of untreated cases The patient was considered to be in a critical condition if the hæmoglobin was below 20%, but even then response to treatment was usually rapid and gratifying Twenty-four hours after admission the patient may look, if anything, more bloodless than when first seen, after forty-eight hours of liver treatment, however, one can say definitely that improvement has begun, even without blood-examination Faint flushing of the conjunctivæ is a sign which makes the clinician feel satisfied about the patient for the time being Every day thereafter improvement is apparent, blood-examination a week after admission shows a gain of at least half a million in red cells, and of 5–10% in hæmoglobin The next week should show the same advance, especially if iron has been added to the liver treatment At the end of a week the œdema and cough should have almost disappeared The temperature settles down in ten days or so, and intercurrent gastro-intestinal and urinary complications usually recover as the anæmia improves At the end of the first week the patient feels much better, and in two weeks she becomes restive Probably she may be prevailed on to stay another week in hospital, a few very severe cases have remained even longer By the end of three weeks improvement is so pronounced that the patient is allowed to go, usually with instructions to continue to take liver This advice is rarely followed but in those cases where a follow-up was possible it was found that the anæmia did not return in that pregnancy Once response to treatment is definitely established labour rarely gives rise to anxiety

Of this series, 53 patients were delivered in hospital, the puerperal morbidity-rate among them was 34%, the prematurity-rate 64%, and the stillbirths and deaths of infants within the first week of life, together, 40%

A follow-up of the cases after discharge from hospital has been carried out as far as possible, but the difficulties are peculiar the people are illiterate and may be unable to give their correct names or addresses As far as can be judged these women recover their normal health some time after discharge from hospital, and relapse has not been observed during the same pregnancy Recurrence of anæmia is common, however, in subsequent pregnancies, 10 of the 100 patients were traced through subsequent pregnancies, and in 8 of them severe macrocytic anæmia developed in the next pregnancy, in 1 case, though the second pregnancy was apparently normal, severe anæmia developed in the third

PROGNOSIS AND MORTALITY-RATE

If the patient is untreated, the outlook is bad unless labour is early The prognosis is good under treatment, provided the patient is not in extremis when first seen and if she is not already in labour If the hæmoglobin is not less than 20% and the red cells not below 1,000,000 recovery is the rule One or two patients under my care had a much lower hæmoglobin value and recovered, but such cases cause anxiety for some time, and must be considered as critical, especially if they go into labour. The prognosis has greatly improved since liver extract suitable for parenteral administration has been available, but as might be expected, the patients are so ill that their ability to take, retain and absorb liver by mouth is uncertain and variable

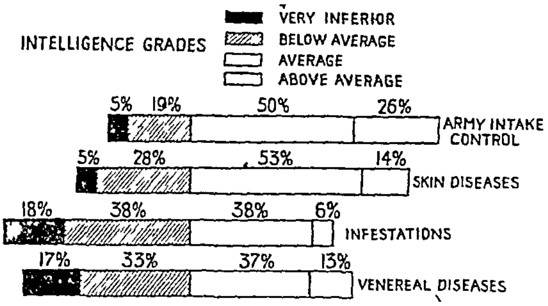
Acute anæmia appearing for the first time in the puerperium may cause anxiety Œdema is not severe and the question of sepsis has to be considered Even a low-grade infection makes the response to treatment less and venereal diseases Statistical analysis, ætiology and clinical features all justify this grouping

The percentage distributions of intelligence grades in the groups and in the control (500 consecutive recruits at a R A M C depot) are set out in table II and are compared diagrammatically in the figure

TABLE II

—	Cases	Grade (per cent)			
		(*a*)	(*b*)	(c)	(*d*)
Army intake control—	500	5	19	50	26
Skin diseases	306	5	28	53	14
Infestations	497	18	38	38	6
Venereal diseases	199	17	33	37	13

It will be seen that " very inferior " intelligence occurs more than three times as frequently in both the infestation and venereal groups as in the control group, while in the skin group it occurs with no greater frequency than in the control Furthermore, all three groups of patients under consideration show a preponderance of subnormal intelligence, least decided in the skin group, and so great in the infestation group that actually as much as 56% fall into the subnormal intelligence grades Mellanby's (1941) recent emphasis on the personal-contact factor in the spread of scabies lends particular interest to the close similarity in the intelligence distributions of the infestation and venereal groups, especially in view of their widely different pathogeneses



Distribution of intelligence grades

An investigation of the intelligence distribution of the individual diseases which form the groups in this paper is in progress

SUMMARY

The intelligence of patients attending a military dermatological clinic has been investigated For the purpose of comparison cases were divided into 3 groups venereal diseases, infestations and other skin diseases

A high proportion of men with " very inferior " intelligence was found in the infestation and venereal-disease groups All three groups showed a higher proportion of subnormal intelligence than the control and among infested patients the proportion of subnormal intelligence amounted to 56%

I wish to thank Lieut Colonel P J Dwyer for giving facilities for this investigation and Prof M Greenwood for his statistical advice

OSLER MEMORIAL IN PHILADELPHIA—The " Old Post House " at Philadelphia General Hospital has been opened as a memorial to Osler because it was here that he taught and practised pathology when professor of clinical medicine in the University of Pennsylvania The house, which had been relegated to the position of the hospital paint shop, has been restored through the generosity of Messrs John Wyeth and Brother, so that it resembles as nearly as possible what it was in Osler's time, and in it hangs the painting by Dean Cornwell, also the gift of Messrs Wyeth, which shows Osler in characteristic attitude addressing a group of residents

MACROCYTIC ANÆMIA
IN PREGNANT WOMEN ON THE GOLD COAST*

BEATRICE A S RUSSELL,
M D EDIN , F R C P E D T M. & H
MEDICAL OFFICER IN THE COLONIAL MEDICAL SERVICE, GOLD COAST

THIS paper is based on a study of 100 cases of macrocytic anæmia selected from the records of the Maternity Hospital, Accra, in the ten years (1928–38) after the hospital was opened , 38 of the cases were under my care The cases constituted about 1% of the total in-patients, but since only severe and definite cases are included this figure does not represent the full incidence of the disease I have included cases complicated by malaria and hookworm and some cases with concurrent urinary infection In all these the anæmia was so profound that I had no hesitation in considering them to be primarily cases of macrocytic anæmia of pregnancy

CLINICAL HISTORY

Detection of anæmia among the dark-skinned by inspection alone is difficult, and slight cases tend to escape notice The prevalence of anæmia in 481 unselected cases attending the maternity hospitals in Accra and Kumasi is shown in the table Macrocytic anæmia, in my 38 cases, appeared to develop rapidly , the duration of symptoms was seldom more than a fortnight In one or two cases admitted to hospital on account of other conditions, severe macrocytic anæmia was observed to develop within a few days

A primipara of 32 weeks maturity, complained of general pains and headache , the hæmoglobin on admission was 55% six days later it had dropped to 38%, and the red cell count was 1,360,000 per c mm

Age-incidence cannot be given, because the patients do not know their ages , 64 were primiparæ and 36 multiparæ , thus in the Gold Coast multiparity is not an important factor in ætiology The stage at which the anæmia developed, in the 106 pregnancies of these 100 women was as follows

Maturity in weeks	Cases	Maturity in weeks	Cases
Under 20	3	31–35	26
20–25	18	36–40	13
26–30	40	Unknown	6

Thus 29 cases occurred in women of less than twenty-eight weeks' maturity, showing that the disease was not uncommon prior to the last trimester period

Concurrent infections —The history of yaws was positive in 18 and negative in 79 cases , 3 were unrecorded , but since the history depended entirely on the statements of the patients these figures are not necessarily—or even probably—correct The Wassermann reaction was investigated in 53 and was found to be strongly positive in 11 and positive or faintly positive in 7 This does not differ significantly from the positive-Wassermann rate of the population as a whole, which is about 32% (Medical Research Institute, Accra)

Malarial parasites were present in 29 cases The incidence of hookworm and urinary infections is noted later

These observations may be compared with the figures obtained in the routine laboratory examination of in-patients in the Accra maternity hospital shown below

Malaria

Blood examinations 6925
Malarial parasites present in 27%

Wassermann Reaction

Examinations	5335	Positive Wassermann rate 32 5%

Fæces

Examinations	1372	Ascaris ova present in 17%

Ankylostome ova present in 16%
Tænia ova present in 1 case

SIGNS AND SYMPTOMS

When the patient is first seen anæmia is usually well advanced and she is complaining of one or more of the

* Abstract of a thesis presented for degree of M D University of Edinburgh, October, 1939

SERUM CALCIUM AND INORGANIC PHOSPHORUS IN PARATHYROID TETANY

THEIR BEARING ON TREATMENT

J DOUGLAS ROBERTSON M D D SC ST AND, D P H
CLINICAL CHEMICAL PATHOLOGIST TO THE MIDDLESEX HOSPITAL
(*Courtauld Institute of Biochemistry*)

AMONG the measures recommended in the treatment of parathyroid tetany by raising the serum calcium are the administration of parathyroid hormone thyroid, calcium salts vitamin D dihydrotachysterol (A T 10) lactose the production of an acidosis, and diets with a high calcium to phosphorus ratio

Parathyroid hormone —It is now clear that the chief function of the parathyroids is the mobilisation of calcium from the bones into the blood-stream Removal of the parathyroids causes calcium to leave the blood, probably to be precipitated in the bones, for as was first shown by Greenwald and Gross (1925) the sudden fall in the serum calcium in tetany is accompanied by a lowering in the calcium excretion. The abstraction of the active principle of the parathyroid glands by Hanson (1923) and Collip (1925) led at once to its employment in the treatment of hypoparathyroidism Albright and others (1929) showed that injection of parathyroid hormone [illegible] any brought about an abrupt increase in the urinary excretion of phosphorus followed by a fall in the blood phosphorus (unless the serum calcium rose above 15 mg per 100 c.cm. when the urinary excretion of phosphorus fell and blood phosphorus rose) and a gradual increase in the urinary excretion of calcium with a gradual but large rise in serum calcium. Several workers have been warned against the employment of parathyroid hormone as a routine measure in the treatment of tetany on the grounds of the danger of overdosage, of loss of effectiveness or of decalcification of the bones if used over long periods, as well as expense

Thyroid —Kunde Oslund Kern (1928, 1931) found that the [illegible] of thyroparathyroidectomised dogs could be temporarily controlled by thyroid feeding After this Aub and others ([illegible]) stated that the administration of thyroid or thyroxin to cases of hypoparathyroidism resulted in a well marked elevation of the serum calcium, and their findings have been [illegible] by Hunter (1930), Shelling (1935) and Means (1937)

Calcium salts —The administration of calcium salts intravenously, intramuscularly or by mouth still remains the chief therapeutic measure in parathyroid tetany When a prompt response is desired calcium is given intravenously as the chloride or gluconate in 10% solutions in doses of 10 c cm Salvesen, Hastings and McIntosh (1924), Smith and Stern[illegible] (1932), and Shelling (1935) have found that the maximum concentration of serum calcium (as much as 100% [illegible]) is reached at the end of the injection, thereafter there is a rapid fall to the previous level in 2–4 hours Calcium gluconate alone can be injected intramuscularly without causing severe inflammatory reactions There is a choice of many salts to be given by mouth but the chloride, lactate and carbonate are most commonly employed, the first because of its solubility and acidotic qualities which promote absorption, the second because of its palatability and the last because of its high calcium content

Vitamin D and dihydrotachysterol (*A T* 10) —Since Holtz (1933) introduced dihydrotachysterol—or A T 10 (antitetanic preparation 10) as it is sometimes called—into the therapy of tetany a vast literature has accumulated on its value According to McLean (1941) the effects of vitamin D and A T 10 are similar if given in comparable doses and there is no reason "to attribute a higher degree of specificity or a lesser likelihood of toxicity to dihydrotachysterol than to vitamin D" One milligramme of calciferol is equivalent to 40,000 international units of vitamin D and this is equal to 0 1 c cm of A.T 10 Much confusion has arisen over the value of vitamin D in the treatment of parathyroid tetany There are two well-defined dosage ranges, the first is antirachitic (700–1000 I U per day), and the second is the dosage necessary to raise a subnormal serum calcium (50,000–200 000 I U per day) According to McLean the higher dosage of vitamin D leads to an increase in the excretion of urinary phosphorus, a fall in serum phosphate and a rise in the serum calcium, while both calcium and phosphorus are added to the blood by liberation of these minerals from the bones Hess, Benjamin and Gross (1931) Jones and Rapoport (1931), and Shelling (1931) have shown that the calcæmic effect of vitamin D in large doses can be produced without calcium feeding Vitamin D in large doses has therefore two distinct actions—it promotes absorption of calcium from the gut and it mobilises calcium and phosphorus from the bones

Lactose —Dragstedt and Peacock (1923) and Inouye (1924) stated that lactose-containing diets protected parathyroidectomised animals against tetany Greenwald and Gross (1929) found this only to be true if large amounts of calcium are also contained in the diets Thus lactose acts only by making the calcium more available

Production of an acidosis —Wilson, Stearns and Janney (1915), using hydrochloric acid and Boyd Austin and Ducey (1926) and Greenwald (1929), using ammonium chloride, studied the effect of acidosis on parathyroid tetany The severity and frequency of the attacks were reduced and this was accompanied by an increased excretion of phosphorus The effect on the serum calcium was variable Anderson and Lyall (1939) found that hydrochloric acid raised the serum calcium of parathyroid tetany above normal

Low phosphorus therapy —The beneficial effects of a low phosphorus, high calcium diet have been substantiated by Shelling and Goodman (1934) Ellsworth (1933), and Anderson and Lyall (1939), who found that low calcium or high phosphorus diets were conducive to tetany whereas high calcium or low phosphorus diets were ameliorative It would appear that the desirable intake of phosphorus daily is not greater than 0 5 g and with this amount of phosphorus 2 g of calcium daily should be taken In discussing the nature of a low phosphorus diet, Shelling has stated it means eating less meat, glands, nuts, milk, cheese and yolk of eggs, and more fruit, vegetables white of eggs, carbohydrate and fat Milk and cheese, which are the chief sources of calcium also have a high phosphorus content

PRESENT INQUIRY

In the present inquiry, a series of cases of postoperative parathyroid tetany (complicating subtotal thyroidectomy for relief of thyrotoxicosis) were investigated and the effect of thyroid calcium salts ammonium chloride and vitamin D (calciferol) on the blood chemistry determined By this study it was hoped to rationalise the treatment of tetany when it occurs as a complication of subtotal thyroidectomy for the relief of thyrotoxicosis In a previous paper (Robertson 1941c) attention has been drawn to transient mild postoperative attacks of tetany due to trauma or infection In such cases there is a fall in serum calcium which invariably rises within a few days or weeks to normal without any calcium or other medication The cases of parathyroid tetany in the present inquiry were all chronic ones ranging from 3½ to 11 years in duration Fluctuations due to changes in the activity of the parathyroids or accessory parathyroid tissue could therefore be reasonably excluded

The chemical methods employed have already been described (Robertson 1941a) except for the measurement of the alkali reserve (Van Slyke 1917) In table I are given details of the seven cases investigated Of these, two (cases 1 and 7) were unable to continue the investigations after thyroid feeding owing to evacuation problems No form of therapy had been received by any patient for at least 1½ years The calcium and phosphorus intakes were calculated from an average of 7–10 daily dietary surveys The gastric analyses were normal and all cases secreted free hydrochloric acid after gruel

---

DR. RUSSELL MACROCYTIC ANÆMIA (*continued*)

[illegible] patients with low hæmoglobin values in the expectation that by so doing severe anæmia may be successfully prevented

I thank the Director of Medical Services of the Gold Coast for permission to publish this paper

satisfactory, and some of these cases tend to become aplastic in type

There were only 5 deaths among the 100 cases treated in hospital This figure is low considering that the anæmia was often severe

TREATMENT

Treatment was by rest in bed, full diet and raw liver or liver extract by mouth or by injection If the patient could take it, ½ lb of raw liver was given daily, finely minced, with salt and pepper, and eaten with orange juice The patients preferred it to Marmite, and there was some evidence that liver was more quickly beneficial In India marmite is the sheet anchor of therapy It was used also in this series, but only in small doses, which probably had little effect Campolon injections were used in all severe case from the middle of 1935 The dose at first was 2 c cm injected into the buttock every second day for 5–7 injections Later it was found that this was often inadequate, and that 4 c cm daily was needed to get a satisfactory result, As the macrocytic anæmia responds to treatment, the underlying and concurrent hypochromic anæmia is unmasked, and a useful response to iron takes place Iron therapy was usually started as soon as the initial response to liver therapy was well established—that is, in five to seven days Iron was given as one of the scale preparations in doses of gr 30 thrice daily, or in conjunction with arsenic

Blood-transfusion has seldom been necessary According to Balfour (1927) when response is unsatisfactory a small transfusion, intravenously or intramuscularly, will give the necessary stimulus towards recovery In the case of a strongly positive Wassermann reaction, it is as well to give a course of neoarsphenamine

Induction of labour is seldom required In a few cases which respond well at first and then remain stationary with hæmoglobin and red cells still at very low figures, it may be desirable to induce labour in the interest of the mother, but the measure is not devoid of risk because of the danger of sepsis developing in the puerperium

In cases discharged from hospital before delivery it has been impossible to insist on continuance of treatment or even to keep track of the patients Those who could be followed up seem to have gone through labour safely even without further treatment The danger of the recurrence of anæmia in future pregnancies can probably be reduced by antenatal supervision and by early treatment of cases showing a low hæmoglobin level

ÆTIOLOGY

According to recent literature macrocytic anæmia is regarded as a deficiency disease due to lack of the hæmopoietic factor necessary to normal blood-formation This lack may be due to several factors of which the three most important are

1 Temporary lack of intrinsic factor in the gastric secretion or to temporary failure of power of assimilation (Strauss and Castle 1932, 1933, Vaughan 1938)

2 Lack of extrinsic factor or of vitamin B_2 in the diet

3 A predisposing iron deficiency anæmia, believed by some writers to be always present before macrocytic anæmia can develop, and due mainly to unsatisfactory diet (Larrabee 1925, Strauss and Castle 1935)

I believe that all of these factors may have some bearing on the prevalence of this form of anæmia in the Gold Coast The sick in the tropics are often afflicted with two, three or four different pathological conditions, and since in any form of ill health the gastric secretion is seriously concerned it is not unreasonable to presume lack of power of assimilation and perhaps temporary lack of intrinsic factor The diet of the people on the Gold Coast is demonstrably poor in vitamin B_2 or extrinsic factor, so that even in health there may be little margin Wills (1939) holds that all cases of anæmia in pregnant women associated with less than 90% of hæmoglobin should be treated If this is taken as the standard, the amount and degree of anæmia on the Gold Coast as shown in the table is grave indeed

Another factor may be the presence of liver disease and its influence on the ability of the body to store or to utilise hæmopoietic substance Goldhamer, Isaacs and Sturges (1934) demonstrated that the normal liver stores hæmopoietic substance, but that if diseased it fails to do so or is unable to release it Clark (1936) reported that disease of the liver appears to be more frequent in Nigeria, where dietetic conditions are similar to those on the Gold Coast, than it is at home He held, as a result of rat experiment, that this is largely due to the poor class of carbohydrates, especially cassava and cocoa-yam, which are largely consumed He considered these roots to be dangerous cyanogenic substances in the absence of a sufficient supply of good-class protein, in some circumstances maize may act in the same way Fairley and his colleagues (1938) found that malaria caused liver damage in Macedonia, and malaria is prevalent on the Gold Coast

BLOOD FINDINGS IN TWO GROUPS OF 481 UNSELECTED PREGNANT WOMEN WITH NO DEFINITE SYMPTOMS OF ANÆMIA

		Under 50	1	10 (3%)

* Colour index unity or over in 23, malarial parasites present in 23 † Malarial parasites present in 94

Factors predisposing to macrocytic anæmia thus appear to be various, but the most important are, I believe, the three first mentioned

To what extent tropical macrocytic anæmia of pregnancy and macrocytic nutritional anæmia in the non pregnant are the same disease has not been finally agreed Balfour (1927) reported cases which appeared to be identical except that pregnancy did not coexist Fairley and his colleagues (1938) suggested that "nutritional" rather than "tropical" macrocytic anæmia was a more suitable term when reporting cases occurring in Macedonia Davidson and Fullerton (1939) refer to *nutritional macrocytic anæmia* and to *macrocytic anæmia of pregnancy* under different headings

My own experience of macrocytic anæmia among non-pregnant women in the Gold Coast is too limited to be of value, but in the cases occurring in pregnancy the problem appears to be essentially one of nutritional defect From observation of the disease and of the prompt relief which follows the administration of liver or liver extract, I consider that macrocytic anæmia is not a disease of pregnancy but a disease associated with pregnancy Pregnancy is the most common and prolonged strain to which young women are subjected, add to this an unsatisfactory diet with the disorder of gastric secretion which is common in pregnancy and the stage is set for breakdown in the blood-forming system In the absence of pregnancy the breakdown would probably not occur, or at least not occur until a more advanced age

SUMMARY

Severe macrocytic anæmia is not uncommon among pregnant women on the Gold Coast, 100 severe cases are analysed

In both treated and untreated cases there is a tendency to premature labour with stillbirth or death of the infant in the first week of life When untreated the maternal mortality is high, but if the anæmia is not too far advanced recovery may be rapid after delivery If anæmia is severe, death rapidly supervenes

Macrocytic anæmia of pregnancy quickly responds to treatment with liver or liver extract, preferably administered by injection The fatality in the present series was only 5% Severe anæmia often recurs in subsequent pregnancies

The more important predisposing factors are unsatisfactory diet, intercurrent disease, especially malaria, and hypochromic anæmia

Many Gold Coast women are anæmic during pregnancy Prevention of this depends largely on improvement in the general standard of living In the meantime the obstetrician must be alert to detect and treat all

Continued at foot of opposite page

Vitamin D (calciferol).—The results are given in table V. In every instance calciferol administration was followed by a rise in the serum calcium. The elevation of the serum calcium was highly significant ($t = 12.7$ and $P < 0.001$) and was present in the postabsorptive state. This rise in the serum calcium occurred in the absence of any orally ingested calcium other than that provided in the diet. No significant changes occurred in the serum inorganic phosphorus ($t = 0.8$, $P = 0.4$).

REGENERATION OF PARATHYROID TISSUE

In a previous paper, Robertson (1941b) attention was drawn to mild forms of parathyroid disturbance, where in the absence of the clinical manifestations of tetany the serum calcium fell. Without any form of calcium therapy within a few weeks the serum calcium rose. Likely causes of this fall in the serum calcium were said to be trauma to the parathyroid glands through manipulation during the operation and disturbance of their blood-supply through œdema, blood-clot or infection. When destruction of the parathyroid glands is present and tetany appears, steps must be taken to increase the serum calcium. Many workers have raised the question of the presence of accessory and regenerative parathyroid tissue in the body which might function during tetany. When therapy designed to raise the serum calcium is being given it is not easy to determine with certainty the part, if any, played by regenerative or accessory parathyroid tissue. In table III of this paper it was shown that, in the postabsorptive state, calcium given by mouth did not elevate the serum calcium. It follows therefore that if any elevation of serum calcium occurs in the postabsorptive state either regeneration of or accessory parathyroid tissue is present.

In table VI, observations on twelve cases of parathyroid tetany are set out. Two cases had no treatment, nine were given calcium lactate by mouth, and one was given a single injection of calcium intravenously. In the postabsorptive state none of these forms of calcium therapy could explain an elevated serum calcium. In every instance there was a rise in the serum calcium above the level during tetany. The mean values of 6.8 mg. per 100 c.cm. and 8.9 mg. were found to have a highly significant difference ($t = 5.95$, $P < 0.001$). It seems that following tetany there is regeneration of or accessory parathyroid tissue. It must be pointed out however that despite the presence of this accessory parathyroid tissue the serum calcium still falls far short of normal. There is a very significant difference between the serum-calcium levels of the so-called chronic tetany with a mean of 8.9 mg. per 100 c.cm. and of the normals published previously (Robertson 1941a) with a mean of 10.39 mg. ($t = 3.32$, $P < 0.01$).

TABLE V—POSTABSORPTIVE STUDY—SERUM CALCIUM, INORGANIC PHOSPHORUS AND ALKALI RESERVE AFTER INGESTION OF 3 G. OF AMMONIUM CHLORIDE DAILY FOR TWO WEEKS. DISCUSSION

Thyrotoxicosis is associated with an excessive calcium excretion, which may lead to an osteoporosis and a normal calcium absorption. The calcium excretion falls to normal with the cure of the thyrotoxicosis. In parathyroid tetany a diminished secretion of parathyroid hormone causes the serum calcium to fall and thus is associated with a diminished calcium excretion and a normal absorption. Treatment of parathyroid tetany aims at raising the low serum calcium and this should be achieved by some mechanism similar in nature to that of parathyroid hormone which controls the release of calcium from the skeleton to the blood-stream. The raising of the serum calcium in tetany by large doses of calcium salts appears to be wrong in principle.

TABLE VI—SPONTANEOUS REGENERATION OF PARATHYROID TISSUE: SERUM-CALCIUM ANALYSES IN POSTABSORPTIVE STATE.

Case	Serum calcium, during tetany	Follow up observations		Treatment if any
		Since attack of tetany	Serum calcium	
	mg. per 100 c.cm.	months	mg. per 100 c.cm.	
1	7.8	6	9	Oral calcium lactate
6	8.4	40	9.1	
2	7.5	62	9	1 injection of 10 c.cm. Calcium Sandoz intravenously.

5	5.4	9	8	
11	5.5	22	7.7	
12	8.7	3	10.2	None
Mean	6.8		8.9	—

When however parathyroid tetany complicates subtotal thyroidectomy for the relief of thyrotoxicosis the treatment should take into account two factors. First, a demineralised skeleton in need of calcium, and a serum calcium requiring elevation. Large doses of calcium meets the first demand, but the second is not so simple. The disadvantages of injections of parathyroid hormone have already been referred to; thyroid feeding has been shown to lower still further the diminished serum calcium; the action of calcium salts is only transitory; therapeutic doses of ammonium chloride while producing a mild acidosis were found not to raise the serum calcium. The administration of a low phosphorus diet has been clearly shown by Shelling and Goodman (1934) and Anderson and Lyall (1939) among others to be very efficacious in raising the diminished serum calcium of tetany. But food restrictions in war-time make it very difficult if not impossible to procure a low phosphorus diet, including as it does fruit, vegetables, white of eggs, carbohydrates and fats. Further a low phosphorus diet is combined with a high calcium intake of at least 2 g. daily. While this intake of calcium can do no harm to subjects with normally functioning parathyroids, in tetany with damaged parathyroids and a diminished calcium excretion it would lead to an unnecessary storage of calcium. Some observations reported in this paper confirm (Himsworth and Maizels's findings in 1940) that vitamin D (calciferol) can raise the reduced serum calcium of parathyroid tetany. When given in adequate doses of 100 000 I.U. daily it raised the serum calcium despite a low calcium and high phosphorus content of the diet (i.e., case 1 in tables I and V). In view of the nature of the disturbed calcium metabolism in cured thyrotoxicosis and parathyroid tetany when these diseases occur in the same patient a suggested line of treatment would be as follows:

1. Large doses of calcium, such as 7 g. of the carbonate or 22.5 g. of the lactate daily should be given for about a year postoperatively to correct the demineralisation resulting from the thyrotoxicosis.

2. The calcium intake should then be reduced to normal requirements (0.7–1 g. daily) and calcæmic doses of vitamin D given (60,000–200,000 I.U. daily according to McLean (1941). The action of vitamin D in such doses resembles that of parathyroid hormone in supplying calcium to the blood-stream from the bones. The serum calcium can be determined from time to time, thus ensuring that no hypercalcæmia results.

In determining the effect of various therapeutic agents on the serum-calcium level in parathyroid tetany account must be taken of regeneration of or the presence of

TABLE I—SUMMARY OF CASES OF PARATHYROID TETANY INVESTIGATED

Case	Age	Since attack of tetany	Since any calcium medication	Daily intake: Calcium	Daily intake: Phosphorus	Maximum secretion of free HCl *	Milk daily
	Years			g		(c cm n/10 NaOH	oz
1	25	3¼	1¼	0 96	1 08	27	16
2	51	5½	5¼	0 36	0 92	45	5
3	38	4	3	0 5	0 8	30	7
4	17	3¼	2	1 2	1 3	24	24
5	31	11	6	1 16	1 36	18	30
6	30	3½	2	1	1 1	10	22
7	44	5¼	2	0 84	1 02	16	12

* By fractional test-meal using gruel (Beaumont, G E and Dodds, E C Recent Advances in Medicine, London, 1941)

Thyroid feeding —The results are given in table II In every instance except one, thyroid administration was followed by a fall in serum calcium The two mean values, 8 51 mg per 100 c cm before and 8 01 mg after thyroid, were found to have a highly significant difference (t = 4 1 P = 0 001), in spite of the small number of cases The value of t was calculated from the individual pair differences

Employing the same statistical methods no significant difference was found in serum inorganic phosphorus before and after thyroid feeding (t = 0 6 and P = 0 5)

In every instance thyroid administration was accompanied by a rise in the serum phosphatase, the mean value rising from 4 77 units to 6 16 This difference was found to be highly significant (t = 4 1, P = 001) If the serum phosphatases of parathyroid tetany are compared with the normals previously published by Robertson (1941a) the two mean values of 4 77 units and 7 795 units are found to have a highly significant difference (t = 3 16 P < 0 01) The two mean values of 6 16 units for parathyroid tetany after thyroid feeding and 7 795 units for normals show no significant difference (t = 1 26 P = 0 2) These investigations indicate that thyroid administration lowers the serum calcium of parathyroid tetany, findings opposed to current belief The serum phosphatase is diminished in parathyroid tetany and thyroid feeding raises it to normal

Calcium salts —In table III are the findings after the daily ingestion of the equivalent of 3 g of calcium for two weeks The analyses were carried out in the postabsorptive state and the phosphate, lactate or chloride were employed No significant difference could be detected in the level of the postabsorptive serum calcium before and after the daily administration for two weeks of these calcium salts in equivalent doses For phosphate (t = 0 92 P = 0 4), for lactate (t = 1 28, P = 0 3) and for chloride (t = 2 11, P > 0 05), the values of t being calculated from the individual pair differences No significant alteration in the serum phosphorus was found to take place after these various calcium administrations

It is well established now (Bauer and Ropes 192 Greenberg and Gunther 1932, Freeman Kant and I 1935) that in normal people the serum-calcium respon to ingested calcium reaches its maximum at the end two hours Preliminary observations showed that cas of parathyroid tetany responded in a similar manne the maximum concentration of serum calcium bei reached at the second hour In table IV are given t variations in the serum calcium and inorganic phospho before and two hours after the ingestion of various solub and insoluble calcium salts The absorption of an inso uble calcium salt will depend on its solution by the fr hydrochloric acid of the stomach All the cases invest gated had a normal secretion of free hydrochloric acid Examination of the results statistically, the value of being calculated from the individual pair differences show that there is no significant difference in the serum calcium before and after calcium phosphate (t = 1 5 and P = 0 1), but that the ingestion of calcium lacta and carbonate produced an elevation of the serum calcium which was highly significant (for lactate t = 5 2 and P << 0 001, and for carbonate t = 4 93 and P < 0 001) The serum inorganic phosphorus was no affected by the ingestion of any of the calcium salts I seems, therefore, *that the efficacy of a calcium salt* i raising the serum calcium does not depend on its solu bility (assuming a normal gastric secretion of free hydro chloric acid) but on its acid radicle

TABLE II—EFFECT OF THYROID FEEDING ON SERUM CALCIU INORGANIC PHOSPHORUS AND PHOSPHATASE

Vitamin D (calciferol) —The results are given in table In every instance calciferol administration was followed by a rise in the serum calcium The elevation of the serum calcium was highly significant (t = 12 7 and P <<< 0 001) and was present in the postabsorptive phase This rise in the serum calcium occurred in the absence of any orally ingested calcium other than that provided in the diet No significant changes occurred in the serum inorganic phosphorus (t = 0 8 , P = 0 4)

REGENERATION OF PARATHYROID TISSUE

In a previous paper, Robertson (1941b) attention was drawn to mild forms of parathyroid disturbance, where in the absence of the clinical manifestations of tetany the serum calcium fell Without any form of calcium therapy, within a few weeks the serum calcium rose Likely causes of this fall in the serum calcium were said to be trauma to the parathyroid glands through manipulation during the operation and disturbance of their blood supply through œdema, blood-clot or infection When destruction of the parathyroid glands is present and tetany appears, steps must be taken to increase the serum calcium Many workers have raised the question of the presence of accessory and regenerative parathyroid tissue in the body which might function during tetany When therapy designed to raise the serum calcium is being given, it is not easy to determine with certainty the part, if any, played by regenerative or accessory parathyroid tissue In table III of this paper it was shown that, in the postabsorptive state, calcium given by mouth did not elevate the serum calcium It follows therefore that, if any elevation of serum calcium occurs in the postabsorptive state, either regeneration of or accessory parathyroid tissue is present

In table VI, observations on twelve cases of parathyroid tetany are set out Two cases had no treatment, nine were given calcium lactate by mouth, and one was given a single injection of calcium intravenously In the postabsorptive state none of these forms of calcium therapy could explain an elevated serum calcium In every instance there was a rise in the serum calcium above the level during tetany The mean values of 6 8 mg per 100 c cm and 8 9 mg were found to have a highly significant difference (t = 5 95 , P << 0 001) It seems that following tetany there is regeneration of or accessory parathyroid tissue It must be pointed out, however, that despite the presence of this accessory parathyroid tissue the serum calcium still falls far short of normal There is a very significant difference between the serum-calcium levels of the so-called chronic tetany, with a mean of 8 0 mg per 100 c cm , and of the normals published previously (Robertson 1941a) with a mean of 10 30 mg (t = 3 32 , P < 0 01)

TABLE V—POSTABSORPTIVE STUDY—SERUM CALCIUM, INORGANIC PHOSPHORUS AND ALKALI RESERVE AFTER INGESTION OF 3 G OF AMMONIUM CHLORIDE DAILY FOR TWO WEEKS LEVELS OF CALCIUM AND INORGANIC PHOSPHORUS AFTER THE DAILY INGESTION OF 2 5 MG OF CALCIFEROL (100 000 I U VITAMIN D) FOR TWO WEEKS WITHOUT CALCIUM ADDITIONAL TO DIET

DISCUSSION

Thyrotoxicosis is associated with an excessive calcium excretion, which may lead to an osteoporosis, and a normal calcium absorption The calcium excretion falls to normal with the cure of the thyrotoxicosis In parathyroid tetany a diminished secretion of parathyroid hormone causes the serum calcium to fall and this is associated with a diminished calcium excretion and a normal absorption Treatment of parathyroid tetany aims at raising the low serum calcium and this should be achieved by some mechanism similar in nature to that of parathyroid hormone which controls the release of calcium from the skeleton to the blood-stream The raising of the serum calcium in tetany by large doses of calcium salts appears to be wrong in principle

When however parathyroid tetany complicates subtotal thyroidectomy for the relief of thyrotoxicosis the treatment should take into account two factors First, a demineralised skeleton in need of calcium, and a serum calcium requiring elevation Large doses of calcium meets the first demand, but the second is not so simple The disadvantages of injections of parathyroid hormone have already been referred to , thyroid feeding has been shown to lower still further the diminished serum calcium , the action of calcium salts is only transitory , therapeutic doses of ammonium chloride while producing a mild acidosis were found not to raise the serum calcium The administration of a low phosphorus diet has been clearly shown by Shelling and Goodman (1934) and Anderson and Lyall (1939), among others, to be very efficacious in raising the diminished serum calcium of tetany But food restrictions in war time make it very difficult if not impossible to procure a low phosphorus diet, including as it does fruit, vegetables, white of eggs, carbohydrates and fats Further, a low phosphorus diet is combined with a high calcium intake of at least 2 g daily While this intake of calcium can do no harm to subjects with normally functioning parathyroids, in tetany with damaged parathyroids and a diminished calcium excretion it would lead to an unnecessary storage of calcium Some observations reported in this paper confirm (Himsworth and Maizels's findings in 1940) that vitamin D (calciferol) can raise the reduced serum calcium of parathyroid tetany When given in adequate doses of 100,000 I U daily it raised the serum calcium despite a low calcium and high phosphorus content of the diet (i e case 1 in tables I and V) In view of the nature of the disturbed calcium metabolism in cured thyrotoxicosis and parathyroid tetany, when these diseases occur in the same patient a suggested line of treatment would be as follows

1 Large doses of calcium, such as 7 g of the carbonate or 22 5 g of the lactate daily, should be given for about a year postoperatively to correct the demineralisation resulting from the thyrotoxicosis

2 The calcium intake should then be reduced to normal requirements (0 7–1 g daily) and calcæmic doses of vitamin D given (60,000–200,000 I U daily according to McLean (1941) The action of vitamin D in such doses resembles that of parathyroid hormone in supplying calcium to the blood stream from the bones The serum calcium can be determined from time to time, thus ensuring that no hypercalcæmia results

In determining the effect of various therapeutic agents on the serum-calcium level in parathyroid tetany account must be taken of regeneration of, or the presence of

TABLE I—SUMMARY OF CASES OF PARATHYROID TETANY INVESTIGATED

Case	Age	Since attack of tetany	Since any calcium medication	Daily intake: Calcium	Daily intake: Phosphorus	Maximum secretion of free HCl *	Milk daily

7	44	5½	2	0 84	1 02	16	12

* By fractional test-meal using gruel (Beaumont G E and Dodds, E C Recent Advances in Medicine, London, 1941)

Thyroid feeding—The results are given in table II In every instance except one thyroid administration was followed by a fall in serum calcium The two mean values, 8 51 mg per 100 c cm before and 8 01 mg after thyroid, were found to have a highly significant difference (t = 4 1 P = 0 001) in spite of the small number of cases The value of t was calculated from the individual pair differences

Employing the same statistical methods no significant difference was found in serum inorganic phosphorus before and after thyroid feeding (t = 0 6 and P = 0 5)

In every instance thyroid administration was accompanied by a rise in the serum phosphatase, the mean value rising from 4 77 units to 6 16 This difference was found to be highly significant (t = 4 1, P = 001) If the serum phosphatases of parathyroid tetany are compared with the normals previously published by Robertson (1941a) the two mean values of 4 77 units and 7 795 units are found to have a highly significant difference (t = 3 16, P < 0 01) The two mean values of 6 16 units for parathyroid tetany after thyroid feeding and 7 795 units for normals show no significant difference (t = 1 26 P = 0 2) These investigations indicate that thyroid administration lowers the serum calcium of parathyroid tetany, findings opposed to current belief The serum phosphatase is diminished in parathyroid tetany and thyroid feeding raises it to normal

Calcium salts—In table III are the findings after the daily ingestion of the equivalent of 3 g of calcium for two weeks The analyses were carried out in the postabsorptive state and the phosphate, lactate or chloride were employed No significant difference could be detected in the level of the postabsorptive serum calcium before and after the daily administration for two weeks of these calcium salts in equivalent doses For phosphate (t = 0 92, P = 0 4), for lactate (t = 1 28, P = 0 3) and for chloride (t = 2 11, P > 0 05), the values of t being calculated from the individual pair differences No significant alteration in the serum phosphorus was found to take place after these various calcium administrations

It is well established now (Bauer and Ropes 19 Greenberg and Gunther 1932 Freeman Kant and I 1935) that in normal people the serum-calcium respon to ingested calcium reaches its maximum at the end two hours Preliminary observations showed that cas of parathyroid tetany responded in a similar mann the maximum concentration of serum calcium be reached at the second hour In table IV are given t variations in the serum calcium and inorganic phosphor before and two hours after the ingestion of various solub and insoluble calcium salts The absorption of an inso uble calcium salt will depend on its solution by the fr hydrochloric acid of the stomach All the cases invest gated had a normal secretion of free hydrochloric aci Examination of the results statistically, the value of being calculated from the individual pair difference show that there is no significant difference in the seru calcium before and after calcium phosphate (t = 1 5 and P = 0 1), but that the ingestion of calcium lacta and carbonate produced an elevation of the seru calcium which was highly significant (for lactate t = 5 2 and P << 0 001, and for carbonate t = 4 93 and P 0 001) The serum inorganic phosphorus was n affected by the ingestion of any of the calcium salts I seems, therefore, that the efficacy of a calcium salt raising the serum calcium does not depend on its solu bility (assuming a normal gastric secretion of free hydr chloric acid) but on its acid radicle

Vitamin D (calciferol).—The results are given in table In every instance calciferol administration was lowed by a rise in the serum calcium. The elevation the serum calcium was highly significant (t = 12.7 and $\ll$ 0.001) and was present in the postabsorptive ase. This rise in the serum calcium occurred in the sence of any orally ingested calcium other than that ovided in the diet. No significant changes occurred in e serum inorganic phosphorus (t = 0.8, P = 0.4).

REGENERATION OF PARATHYROID TISSUE

In a previous paper, Robertson (1941b) attention was wn to mild forms of parathyroid disturbance, where the absence of the clinical manifestations of tetany e serum calcium fell. Without any form of calcium erapy, within a few weeks the serum calcium rose. ely causes of this fall in the serum calcium were said b trauma to the parathyroid glands through mani- ation during the operation and disturbance of their od supply through œdema, blood-clot or infection. en destruction of the parathyroid glands is present tetany appears, steps must be taken to increase the um calcium. Many workers have raised the question the presence of accessory and regenerative parathyroid e in the body which might function during tetany. therapy designed to raise the serum calcium is given, it is not easy to determine with certainty part, if any, played by regenerative or accessory thyroid tissue. In table III of this paper it was n that, in the postabsorptive state, calcium given by th did not elevate the serum calcium. It follows efore that, if any elevation of serum calcium occurs the postabsorptive state, either regeneration of or cessory parathyroid tissue is present.

In table VI, observations on twelve cases of parathyroid tetany are set out. Two cases had no treatment, nine were given calcium lactate by mouth, and one was given a single injection of calcium intravenously. In the postabsorptive state none of these forms of calcium therapy could explain an elevated serum calcium. In every instance there was a rise in the serum calcium above the level during tetany. The mean values of 6.8 mg per 100 c cm and 8.9 mg were found to have a highly significant difference (t = 5.95, P $\ll$ 0.001). It seems that following tetany there is regeneration of or accessory parathyroid tissue. It must be pointed out, however, that despite the presence of this accessory parathyroid tissue the serum calcium still falls far short of normal. There is a very significant difference between the serum-calcium levels of the so-called chronic tetany, with a mean of 8.9 mg per 100 c cm, and of the normals published previously (Robertson 1941a) with a mean of 10.39 mg (t = 3.32, P < 0.01).

DISCUSSION

Thyrotoxicosis is associated with an excessive calcium excretion, which may lead to an osteoporosis, and a normal calcium absorption. The calcium excretion falls to normal with the cure of the thyrotoxicosis. In parathyroid tetany a diminished secretion of parathyroid hormone causes the serum calcium to fall and this is associated with a diminished calcium excretion and a normal absorption. Treatment of parathyroid tetany aims at raising the low serum calcium and this should be achieved by some mechanism similar in nature to that of parathyroid hormone which controls the release of calcium from the skeleton to the blood-stream. The raising of the serum calcium in tetany by large doses of calcium salts appears to be wrong in principle.

TABLE VI—SPONTANEOUS REGENERATION OF PARATHYROID TISSUE. SERUM CALCIUM ANALYSES IN POSTABSORPTIVE STATE

When however parathyroid tetany complicates subtotal thyroidectomy for the relief of thyrotoxicosis the treatment should take into account two factors. First, a demineralised skeleton in need of calcium and a serum calcium requiring elevation. Large doses of calcium meets the first demand, but the second is not so simple. The disadvantages of injections of parathyroid hormone have already been referred to; thyroid feeding has been shown to lower still further the diminished serum calcium; the action of calcium salts is only transitory; therapeutic doses of ammonium chloride while producing a mild acidosis were found not to raise the serum calcium. The administration of a low phosphorus diet has been clearly shown by Shelling and Goodman (1934) and Anderson and Lyall (1939), among others, to be very efficacious in raising the diminished serum calcium of tetany. But food restrictions in war-time make it very difficult if not impossible to procure a low phosphorus diet, including as it does fruit, vegetables, white of eggs, carbohydrates and fats. Further, a low phosphorus diet is combined with a high calcium intake of at least 2 g daily. While this intake of calcium can do no harm to subjects with normally functioning parathyroids, in tetany with damaged parathyroids and a diminished calcium excretion it would lead to an unnecessary storage of calcium. Some observations reported in this paper confirm (Himsworth and Maizels's findings in 1940) that vitamin D (calciferol) can raise the reduced serum calcium of parathyroid tetany. When given in adequate doses of 100,000 I U daily it raised the serum calcium despite a low calcium and high phosphorus content of the diet (i e case 1 in tables I and V). In view of the nature of the disturbed calcium metabolism in cured thyrotoxicosis and parathyroid tetany, when these diseases occur in the same patient a suggested line of treatment would be as follows:

1. Large doses of calcium, such as 7 g of the carbonate or 22.5 g of the lactate daily, should be given for about a year postoperatively to correct the demineralisation resulting from the thyrotoxicosis.

2. The calcium intake should then be reduced to normal requirements (0.7–1 g daily) and calcæmic doses of vitamin D given (60,000–200,000 I U daily according to McLean (1941). The action of vitamin D in such doses resembles that of parathyroid hormone in supplying calcium to the blood stream from the bones. The serum calcium can be determined from time to time, thus ensuring that no hypercalcæmia results.

In determining the effect of various therapeutic agents on the serum-calcium level in parathyroid tetany account must be taken of regeneration of, or the presence of accessory, parathyroid tissue These factors appear to come into play during the year after the attack of tetany For comparative studies the blood for calcium estimation should be withdrawn at standard times in relation to food and medicines

SUMMARY

A series of seven cases of parathyroid tetany of 3½–11 years' duration have been investigated

Thyroid feeding depressed the serum calcium and had no effect on the serum inorganic phosphorus The serum phosphatase was diminished in tetany and thyroid feeding raised it to normal

The ingestion of 3 g of calcium daily, as the lactate, chloride or phosphate for two weeks produced no significant changes in the serum calcium or inorganic phosphorus

Significant elevations of the serum calcium were found *two hours after the ingestion of calcium lactate and* carbonate Calcium phosphate produced no significant rise in the serum-calcium level The ability to raise a depressed serum calcium appears to depend not on the solubility of the calcium ingested but on its acid radicle

Ammonium chloride in doses of 3 g daily for two weeks produced a mild acidosis, but was without effect on the serum calcium or inorganic phosphorus

Vitamin D (calciferol) in doses of 100 000 international units daily for two weeks produced very significant elevations in the serum calcium and was without effect on the inorganic phosphorus

After an attack of parathyroid tetany parathyroid tissue seems to regenerate Despite this regeneration or the presence of accessory parathyroid tissue the serum calcium still falls far short of normal

The treatment of parathyroid tetany when it complicates the cure of thyrotoxicosis should include the ingestion of large doses of calcium salts only until the decalcification of thyrotoxicosis has been corrected Thereafter the treatment should aim at imitating the action of parathyroid hormone Vitamin D (calciferol) in adequate or calcæmic doses had such a therapeutic effect

I am grateful to Prof E C Dodds for his criticism of this paper, Mr A L Bacharach of Messrs Glaxo Laboratories for generous supplies of calciferol and for help on statistics, Mr S H White and his staff of the Pharmaceutical Department, Middlesex Hospital, for much helpful advice, and the honorary staff of the Middlesex Hospital for permission to investigate their cases

RESECTION OF HEAD OF PANCREAS AN DUODENUM FOR CARCINOMA

RODNEY MAINGOT, F R C S
SENIOR SURGEON TO THE SOUTHEND GENERAL HOSPITAL AND TO T
ROYAL WATERLOO HOSPITAL, LONDON

THE first successful resection of the duodenum and portion of the pancreas for carcinoma involving the ampulla of Vater and adjacent pancreatic head was reported by Whipple, Parsons and Mullins (1935) Later, Whipple (1938) collected and reported on 11 cases in which duodenectomy and partial pancreatectomy had been performed for malignant growths localised to the lower reaches of the common bile-duct or to the head of the pancreas and of these 6 survived operation

The operations were, in many essential respects, similar two stage procedures At the first operation, biliary obstruction was overcome by anastomosing the gall bladder to the stomach or to a loop of proximal jejunum, after which a posterior gastrojejunostomy was performed The first operation was completed by ligating the supraduodenal portion of the common bile duct and by tying the gastro duodenal artery in continuity in order to diminish the blood supply to the carcinomatous area After an interval of 2-3 weeks, by which time it was hoped that the patient would show an all round improvement following an intensive course of treatment, the second operation was carried out This consisted in thoroughly mobilising the duodenum and the head of the pancreas by Kocher's method, transecting the antrum of the stomach close to the pyloric ring or dividing the beginning of the duodenum between crushing clamps, after which the distal part of the third portion of the duodenum was divided between enterotomes, and a generous wedge-shaped area of the head of the pancreas, or maybe the entire head, up to or including its attenuated neck, was cut away together with the attached and now liberated U shaped duodenum After this wide resection the proximal and distal duodenal stumps embraced by the *enterotomes* were oversewn with silk and securely invaginated with purse string sutures The duct of Wirsung was, as a rule, picked up and ligatured, the oozing cut surface of the pancreas oversewn with a continuous locking stitch and then finally sealed off with an omental graft The operative field was drained with a strip of corrugated rubber, a Penrose tube, or a piece of guttered plastic glass In some of the cases the abdominal incision was closed with a series of through and through interrupted sutures of stainless alloy steel wire to guard against the possibility of dehiscence of the wound or post operative eventration

Orr (1941) gives a detailed and tabulated account of all the cases which have been reported to date Of the 15 patients subjected to these two-stage radical excisions, 5 (33 3%) died as a result of the operation, while of the remaining 10 patients, 3 later succumbed to metastatic implants in the liver, 2 from stenosis of the stoma which had been fashioned between the gall-bladder and the stomach or between the gall-bladder and a loop of proximal jejunum, and 1 from bile peritonitis Only 4 were alive at the time of his publication These figures are so disheartening that one may well ask if such heroic measures as partial pancreatectomy and duodenectomy for carcinoma are, in fact justifiable On the other hand, it is well to remember that many of the tumours of the head of the pancreas and of the ampulla of Vater are localised and resectable even at the time of the patient's death, that 60% show no evidence of metastases at operation or at autopsy, that the majority are lethargic in growth and are comparatively benign in character, and that in the present state of our knowledge radical resection offers the only hope of cure

In my opinion, success in this difficult field of visceral surgery is not likely to be achieved in the future unless cases of obstructive jaundice are submitted to inquiry by operation more promptly than obtains at the present time, and until the technical details of the two stage procedure, as so accurately described by Whipple (1938) Brunschwig (1937), Illingworth (1939), Moreland and Freeman (1941), and Ransom (1938) are thoroughly mastered by abdominal surgeons Illingworth (1939) was the first British surgeon to publish a case of resection of the duodenum and head of the pancreas by this two stage method His patient after putting up a splendid fight died from bile peritonitis on the 43rd post-operative day

The following is an account of a case of carcinoma of the ampulla of Vater, in which during the performance of a straightforward cholecystectomy for cholesterosis and gall stones a small cancer of the terminal part of the common bile-duct unfortunately escaped detection, but 6 months later it was possible to restore the patient to health by the radical two-stage procedure

CASE-HISTORY

A married woman, aged 53 was admitted to the Southend General Hospital on May 10, 1940, complaining of flatulent dyspepsia and attacks of bilious vomiting She stated that for some 2–3 months she had suffered from wind and a feeling of distension after meals and that there would be a dull aching pain in the pit of the stomach or below the right rib, which at times passed through the centre of the back There was no history of jaundice or attacks of biliary colic, although about ten days before admission she had had what she described as a bilious attack for 2 days, during which time she vomited large amounts of frothy, yellow stained fluid Her bowels worked regularly and the motions were dark brown in colour There were no symptoms referable to the urinary or genital tract She was a sallow thin patient in good condition heart and lungs clear some tenderness in the region of the gall-bladder which, however, was not palpable No mass could be detected in the abdomen Rectal and vaginal examinations were negative A complete blood investigation showed a slight degree of secondary anæmia No abnormal constituent could be detected in the urine A Graham dye test supported the diagnosis of chronic cholecystitis associated with gall stones A barium meal X-ray examination was not carried out, nor were specimens of the stools tested for occult blood

First operation cholecystectomy—On May 22 the abdomen was explored through a right subcostal muscle splitting incision The stomach was normal, there was no evidence of duodenal ulcer, the gall bladder appeared normal but contained three small stones After displaying the three ducts, a retrograde cholecystectomy was undertaken As the biliary passages appeared healthy and contained no calculus, they were not probed nor was the head of the pancreas or the second portion of the duodenum examined The abdominal incision was approximated in the usual manner and a rubber drain was led down to the stump of the cystic duct The excised gall bladder was slit open and examined It was a typical strawberry gall bladder containing three cholesterol stones Postoperative convalescence was stormy and in spite of gastric aspiration with a Ryle's tube the patient had several bouts of intractable vomiting She rapidly became dehydrated and emaciated in spite of intravenous infusions and other supportive measures including blood transfusions A barium meal X-ray examination was attempted but this failed in its object as the patient collapsed during the screening Shortly after this she improved slowly, the vomiting ceased altogether, she gained in weight, and was eventually discharged to a convalescent home on June 16

She was readmitted to the General Hospital on Dec 6, 1940, nearly 6 months later According to the case sheet, three weeks after leaving hospital she had had another attack of abdominal pain and this was followed by vomiting The attacks became recurrent, 12 days being the longest free period In the attacks she got gradually increasing distension of the upper abdomen, accompanied by colicky pain, then she would vomit large quantities of bitter fluid She had recognized food taken on the previous day in the vomited material She said she had lost 1½ st in weight in 4 months and that she was steadily going downhill She was pale, thin and weary, heart and lungs clear, blood pressure 110/70 mm Hg Abdomen scar sound, but much epigastric distension and gurgling and splashing sounds elicited on palpation No mass felt Nothing abnormal discovered in the pelvis Blood examination showed a fairly severe microcytic anæmia The urine was free of bile, but contained a trace of albumin Barium meal X-ray examination stomach and duodenum distended, with an appearance suggesting either a filling defect due to neoplasm in the second part of duodenum, or an obstruction due to bands

Second operation gastrojejunostomy and duodenotomy—On Dec 8 the abdomen was opened through a long right upper transrectus muscle splitting incision It was at once evident that satisfactory exploration was impossible until the bloated stomach, which occupied the entire upper abdomen, was deflated The anæsthetist was accordingly instructed to pass a small Ryle's tube through the nostril into the stomach, and when this was done the viscus immediately collapsed The first and second parts of the duodenum were much distended and the muscular coats hypertrophied On invaginating the anterior wall of the second portion of the duodenum opposite the *papilla* of Vater, a circular ulcer with a diameter of approximately 1 in and with hard everted rolled over edges could be felt projecting into the lumen of the gut The tumour mass could be traced to the adjacent portion of the head of the pancreas, which was of metallic hardness and inflexible The whole tumour could, however, be pulled upwards and moved freely from side to side, and did not appear to be anchored to the vulnerable inferior vena cava The anterior wall of the second portion of the duodenum was incised for 2 in, and after retracting the edges of the gut with Allis forceps and sucking out the contents of the duodenum with a suction tube a good view of the interior of the duodenum with its contained cancerous ulcer could be obtained The duodenotomy incision was then closed with a three tier suture and a posterior gastrojejunostomy with a vertical stoma was fashioned without the aid of clamps No enlarged lymph nodes could be felt in the region of the growth, and the liver surface was smooth and even The common bile duct was moderately distended, and I was tempted to complete the first stage of the operation by anastomosing the choledochus to the small intestine However, after the gastro jejunostomy the patient was in poor condition, so the abdominal incision was closed expeditiously with a series of interrupted floss silk sutures The gastroduodenal artery was not ligated in continuity nor was a fragment of the tumour removed for microscopic investigation The patient had an uneventful convalescence after the first stage operation and was able to take fluids and semi-fluid nourishment without restraint, but towards the end of the second postoperative week the conjunctivæ became noticeably tinted with bile and the motions were putty coloured

Third operation excision of duodenum and head of pancreas, choledochojejunostomy and entero anastomosis—On Dec 28 the previous vertical epigastric incision was reopened and the silk sutures were removed The pylorus and the first, second and third parts of the duodenum were liberally freed and mobilised The portal vein was exposed and a number of tributaries were found running into it from the first and second parts of the duodenum Some of these veins were very large and thin-walled Each was ligatured in two places with fine silk, and then divided The pyloric antrum was transected between clamps and the proximal end of the stomach invaginated and buttressed with adjacent omentum The common bile duct, which was about the size of my middle finger, was cut across low down between hæmostats, and the duodenum and the growth were freed from the right side and pulled over to the left (medially) together with the head of the pancreas The neck of the pancreas was then divided between hæmostats, and the remaining stump was oversewn and covered with an omental graft The third part of the duodenum towards the duodenojejunal flexure was severed between the crushing forceps, and the distal end invaginated with a silk purse string stitch The growth, the duodenum and the head of the pancreas were then removed intact A loop of proximal jejunum some 18 in below the previous gastrojejunostomy was brought up over the transverse colon to the cut end of the common bile duct and an end-to side anastomosis was performed, two layers of continuous sutures of fine silk being used After this a small side to side anastomosis between the ascending and descending limbs of jejunum was made to deflect the intestinal contents away from the biliary passages

The operative field was drained with a large piece of corrugated rubber and the abdominal incision drawn together with interrupted sutures of floss silk and deknatel The ducts of the pancreas were not specifically seen after the neck of the gland was transected, but were merely oversewn with a running mattress suture and protected with a pad of omentum

Postoperative progress—It took the patient about 6 weeks to recover from this operation The abdominal wound became infected and there was considerable discharge of thin purulent fluid through the lower portion of the incision After extraction of the silk sutures the wound slowly healed, leaving a raised keloid scar The jaundice subsided in the third postoperative week The stools were pale brown and semi-fluid for about 17 days, but after that they were well-formed, dark brown and inoffensive. There was no diarrhœa. The patient was given an alkaline mixture containing iron and arsenic 3 times a day, pancreatic extracts, and a semi-solid diet rich in fats sugars and the essential vitamins. She slowly gained in weight, and was discharged from hospital on Feb 6 1941. She was re-examined on June 31 when she was well had gained a stone, and was doing her own cooking. On Aug 6 the surgical registrar saw her and stated that she was looking well. The stools were formed, she was taking pancreatic extract and having only one bowel action a day with the aid of paraffin.

Pathologist's report—The specimen consists of the pyloric end of the stomach, the first, second and about half of the third portion of the duodenum, and the whole head of the pancreas a portion of the neck of the gland and the lower portion of the common bile-duct. There is a circular malignant ulcer with a diameter of approximately ¾ in occupying the second part of the duodenum and involving the papilla the ampulla of Vater and the adjacent head of the pancreas. A probe can be passed through the common duct and then through the centre of the base of the malignant crater. The carcinomatous process appears to have begun either in the ampulla of Vater or in the papilla itself. On microscopical examination, the growth was a columnar-celled tubular carcinoma, exact site of origin doubtful. Only a small area of pancreas was involved in the malignant process.

SUMMARY

The first successful resection of the duodenum and of the whole or a portion of the head of the pancreas including the neck, for carcinoma involving the lower reaches of the common bile-duct and adjacent creatic head was reported in 1935.

Since then only 15 patients have been subjected two-stage radical excisions. These consisted of a liminary cholecysto-enterostomy or choledocho ente tomy combined with gastrojejunostomy and follo some two weeks later by a wide resection of the duoden and the head of the pancreas.

Of these 15 patients 5 died as a result of the operati while of the remaining 10 patients, 3 later died f metastases in the liver, 2 from stenosis of the stoma which had been fashioned between the gall-bladder and the stomach or between the gall-bladder and a loop of proximal jejunum, and 1 from bile peritonitis. Only 4 are alive today.

Only 1 case of successful resection of the duodenum and a portion of the pancreas involving the ampulla of Vater for carcinoma has been reported in Britain. This patient died on the 43rd postoperative day from general peritonitis.

An account is here given of the radical treatment of cancer of the head of the pancreas and of the ampulla of Vater by the two-stage procedure and a case report is presented. The patient enjoyed fairly good health for nine months, but died from implants in the liver eleven months after the last operation.

Reviews of Books

Conditioned Reflexes and Psychiatry

Vol II[1] IVAN PETROVITCH PAVLOV, late director of the physiological laboratories of the Institute of Experimental Medicine, Leningrad. Translated and edited by W HORSLEY GANTT, M D. London Lawrence and Wishart. Pp 199. 8s 6*d*

FEW psychiatrists have appreciated the zest and thoroughness with which Pavlov applied himself to the study of their problems in the last eight years of his life. His physiological method was valid for this field too, he believed and he set himself to apply the lessons learned by animal experiment to the abnormal behaviour of human beings, so variously interpreted by psychologists. The scattered lectures and articles in which his arguments and conclusions were advanced are now brought together, whether they can help the clinician to do his work better or can stimulate fruitful research is still a doubtful question, but the brilliance and honesty of the attempt are beyond dispute. No-one would guess from internal evidence that these were the writings of a man who had been unacquainted with clinical psychiatry until he applied himself to it at the beginning of his ninth decade. In 1930 he spoke of the need to promote "the natural and unavoidable approximation and final fusion of psychology with physiology, the subjective with the objective. The most common example of this blending obviously exists in mental diseases" He therefore made it his business to see a great many psychiatric cases, but he did not make vain pretensions, thus in 1934 he wrote "I am no clinician—I have been and remain a physiologist—and, of course, at present, so late in life, would have neither the time nor the possibility to become one" Clinical psychiatrists will none the less learn from his suggestions. The book follows on the "Lectures on Conditioned Reflexes," and the two volumes contain all Pavlov's published lectures from 1903 until his death. The translation has been admirably done by Dr Horsley Gantt whose years of study and friendship with Pavlov qualify him for the task. Dr Gantt has written, as an introduction, a critical appreciation and biographical sketch of Pavlov's closing years which is vivid and just.

Ophthalmic Nursing

(3rd ed) MAURICE H WHITING, M B Camb F R C S. London J and A Churchill. Pp 157. 6*s*

THE new edition of this popular book should be specially useful in training nurses without previous experience of ophthalmic work. The early chapters on anatomy and physiology are concise but sufficient, except perhaps that a fuller description of the orbit would help to clarify the relations of the eye and the nose. The second half of the book gives sound advice on the nursing of operative and non-operative cases, and on theatre technique, but there are one or two omissions, for example, the actual technique for obtaining a conjunctival culture is not explained, and the nurse is not told how and when to sterilise ocular drops and lotions. The upkeep and care of special instruments such as the tonometer, perimeter, slit-lamp and Edridge Green lantern should be included, since these are maintained by the outpatient nurse, and a description of the ring or Haab giant magnet would add to the interest of the book. More emphasis might have been laid on the importance of knowing the type of injury commonly associated with an intraocular foreign body, and a busy staff nurse would welcome a more convenient way of examining the eyes of an obstreperous child than the one described. The section on the value of sulphonamides might mention their curative value in hypopyon ulcer. Gas injuries of the eye based on experience in the last war are well described, but it is a pity that nothing is said of injuries caused by incendiary and explosive bombs in this one.

A Textbook of Physiology

(7th ed) W D ZOETHOUT, Ph D, and W W TUTTLE, Ph D. London Henry Kimpton. Pp 743. 22*s* 6*d*

THIS American book has deservedly run through many editions, it is a complete elementary review of physiology and takes in such aspects of general and chemical physiology and histology as are necessary. It has been kept well up to date, and the illustrations, a mixture of the new and the rather old-fashioned, are instructive. The chapters are introduced by a list of cross references to related topics, the derivation of new terms is indicated, and at the end are a glossary of technical terms and a list of prefixes and suffixes. The work fully meets the needs of those studying physiology up to a standard somewhat lower than that required of medical students, but the balance of the book is so good that it would serve admirably as a jumping off place for independent folk who like to cull their knowledge from various sources.

THE LANCET

LONDON SATURDAY DECEMBER 27, 1941

WHEN DOC MEETS DOC

"It isn't the prescription that I give," said a great physician, "but the pat on the shoulder with which I give it"

"There is one thing at which the G P is supreme, and that is psychology"

"That eyewash, suggestion, or what you will that does the ordinary patient a power of good"

Thus among ourselves do we describe, in varying terms, that aptitude for handling the sick man s mind which TROTTER included among the attainments of the good doctor As we grow older we tend to play upon it, we have said the same thing so often and still have to say it again, and say it as though it were entirely new and the product of the most recent research One will sit down slowly in his chair looking at the window while he glances at the patient to see that his mind is tuned in to the oracle and will blurt it out or slowly roll it over his tongue according to his judgment of the patient s mentality Another will wash his hands and begin as he picks up the towel, finally bringing out his most impressive sentence as he puts it down again with a little jerk As we pocket our fee we may think what an old scoundrel we have been, but one day being tired or pressed for time, we omit some part of our technique and fail to get our advice across So the by-play is an essential adjunct to the advice This is with the ordinary patient, but what when the patient is a doctor? All must then go by the board The doctor knows the tricks of his neighbour's trade, he has too often seen that flick of the towel and may even have copied it himself Then it is apt to be "Well, old man, you might try such and such, though I don't suppose it really does any good," or "By all means have some radiotherapy, though as you know it has no specific action on the tissues"—plain, unadulterated science with no art to back it up

Should this be so? The doctor is as human as anyone else, with fears and anxieties of which the layman knows nothing and which are more difficult to allay The successful doctors' doctor must use another and a more tedious technique This is likely to include a great expenditure of time, a repetition of examination, a lengthy critical discussion in an undertone, and a complete absence of all those trivialities which some call humbug—the very characteristics, in fact, which do not attract the ordinary patient Every teaching hospital carries on its staff one man who knows this technique to perfection, but knows no other Such a man has but little practice, though doctors flock to him when wives and children s lives are at stake Many a doctor owes the life of his wife or firstborn to him and yet has never been able to send him a paying patient He is fortunate if he has private means, for man cannot live on gratitude and presentation silverware alone

This relationship of doctor to doctor may be fraught with risk A frightened junior may ask his senior about some lesion at that time slight but with grave potentialities Thus a young surgeon pricked his thumb when doing an acute streptococcal mastoid Next day an ominous red line had reached his wrist, and he said casually to his chief Look at this, would you lie up with it?'—and his chief as casually replied 'I shouldn't" He did not realise that that young man was frightened for his life, but was more afraid to show it, and this was his way of asking his chief to be his doctor A junior at two hospitals asked two seniors to wash out his antrum from time to time, and each did so thinking the other was in charge of the case and that he was merely doing a bit of handicraft to help An acute pan-sinusitis supervened with septicæmia No tragedy came of these cases, but there have been others—not always on the surgical side and not always in hospital—where a young doctor s life has been cut short because he has had no real medical attention at all The moral is this Refuse to discuss a doctor s ailment with him unless you are being asked to treat him But if you are, don't let him share the responsibility, treat him as you would any other patient And when you yourself are ailing choose your doctor as decisively as you choose your solicitor, and put yourself as unreservedly in his hands

HEAD INJURIES

JUDGING by the amount being written about them there is a growing realisation of the importance of head injuries, so that these cases may no longer be stuck away in the corner of a hospital ward as something of a nuisance and left to run their course The total number of head injuries resulting from air-raids has been nothing like as large as was expected, but SHEPHERD found 14% of such injuries in a series of 245 air-raid casualties reported on another page, a heavier incidence than in any other regional group, and the increase in road accidents brought about by war-time motoring has accounted for many more cases Much can be done in the way of prevention Protective headgear for the fighting man went out of fashion with the transition from hand-to-hand combat to the lead and steel missile, but the reappearance of the steel helmet in the last war undoubtedly saved many casualties In less serious pursuits, American footballers have for long worn a padded leather helmet to lessen the incidence of concussion in that robust game, and from the speedway and dirt-track we learned the virtues of the crash helmet, especially for motor-cyclists CAIRNS's studies in this war are a cogent argument for insisting that all motor-cyclists should adopt this simple and efficient protection Industrialists have been slow to learn these lessons but MILLER[1] reports that the incidence of head injuries among the South African miners has been greatly reduced by the adoption of the "hard hat," and the fashion will doubtless spread among other classes engaged in dangerous occupations The appalling number of road accidents demands, even in these times, a more vigorous and persistent propaganda campaign for safer use of the roads by motorist, cyclist and pedestrian alike

Most recent writers emphasise the importance of proper treatment of the scalp wound Too often these wounds suppurate, with grave or even fatal complications Adequate excision and thorough cleansing are first principles, but the possibility must be borne in mind that an apparently trivial scalp wound hides a penetrating wound of the skull or brain for which something more is required, and a good case can be made for X-ray examination in every case not obviously a simple laceration A problem as yet unsolved is the correct treatment of traumatic cerebrospinal rhinorrhœa, usually resulting from a fracture through the frontal or ethmoidal air sinuses O'CONNELL[2] considers that immediate closure of the fistula is not necessary, and the natural barrier formed by the scar is at least as good protection against infection from the air sinuses as is an artificial closure reinforced with a fascial graft Others have had the unhappy experience of meningitis arising in the early days after the injury, perhaps while spontaneous closure is being hopefully awaited, and in some of these cases chemotherapy will not save the patient's life There are cases, too of a fistula apparently closing spontaneously, only to leak again some weeks or months later, and a fulminating meningitis may be fatal before treatment can be instituted Because of these risks some maintain that early closure of the fistula is preferable to the uncertainty of spontaneous healing No single person's experience is yet large enough to justify definite pronouncement, but if the centres dealing with large numbers of head injuries are keeping records and following these patients the answer should be forthcoming in a few years The treatment of compound fractures of the vault is more generally agreed on but the same cannot be said about what should happen to a foreign body lodged at some depth in the brain There seems no doubt that unless the search can be made by someone accustomed to the technique it is better not made at all Even in the hands of specialists more harm and disability may result from removing a foreign body than from leaving it where it is Individual cases will have to be dealt with on their merits, with the balance weighted in favour of conservatism

---

[1] Miller, L E *Sth Afr med J* 1941, 15, 331

Not enough has yet been said about rehabilitation There are special centres for dealing with head injuries and their sequels in the military population, but the problem in these cases is often complex and not strictly applicable to civil life There is a need for similar centres for civilian injuries, and the insurance companies might find it to their advantage to make a start in this direction The present machinery of litigation and compensation often perpetuates the invalidism from these as from other injuries, and a rehabilitation centre should be able to give decisions which would shorten the period of invalidism Apart from such institutional treatment we need to get away from the rule-of-thumb treatment of concussion—some cases need only three days in bed, while others may require three weeks or longer, depending on the individual's reaction to the injury The lay public needs to be weaned from the idea that a person who has had a fractured skull is necessarily maimed, mentally or physically With this belief would go the darkened room and the dark glasses, and the whole panoply of a mental illness If the patient recovers from the injury without gross cerebral damage he should be expected to make a fairly complete mental and physical recovery Anything short of that in the great majority of cases would imply faulty management in the early stages of convalescence

REFRACTORY ANÆMIA

WHEN the hæmopoietic property of liver ext and the proper use of iron salts were firmly establ it seemed as if treatment of the primary blood orders would henceforth be simple and satisfac From the first it was recognised that leukæmia the classical aplastic anæmia had to be excluded a that certain hæmolytic anæmias required spec treatment , but these were a minority The pathol gist's report showing an anæmia with a high colou index was thus the signal for liver extracts and favourable prognosis Mostly this optimistic foreca was fulfilled, but sometimes the response was di appointing—liver extracts were changed, iron w given, in the end blood-transfusion was usually need and the outlook was gloomy These unfortuna patients were in such striking contrast to those wh responded normally to treatment that they were soo noticed and reports of " pernicious anæmia refracto to liver treatment " began to appear In 19 ISRAELS and WILKINSON[1] showed that there was fact a group of patients in whom the clinical featur blood-picture, and histological changes in the bon marrow closely resembled pernicious anæmia but wh in varying degrees of completeness, failed to respon to liver extracts of tested potency , a notable p was that achlorhydria, so typical of true pernici anæmia, was not present This group was name achrestic anæmia and later[2] it was reported th sternal-marrow biopsies studied by the dry-sme technique were also of the pernicious anæmia ty with megaloblastic hyperplasia Other writers hav reported patients in whom a normoblastic hyperplas of the marrow was found and who similarly failed respond to treatment , this anæmia was sometim called " pseudoaplastic "

The same problem forced itself on the attention workers at the Rockefeller Institute in New York an in 1939 C P RHOADS[3] summarised the conclusion reached After all anæmias which could be attribute to cancer, Hodgkin's disease, nephritis, cirrhosis the liver or leukæmia had been rigidly excluded, the remained a group of primary anæmias whose cour did not respond to any of the standard treatments these were intensively studied and a full report ha recently been given by BOMFORD and RHOADS[4] o 66 such cases The natural history was carefull noted , the histology of the bone-marrow was studie by sternal biopsy and at autopsy , fractional gastr analyses were made , changes in the urobilinoge excretion were used to estimate liver function porphyrin excretion was studied and the copro porphyrin isomers were isolated in 6 cases , the excre tion of glucuronates was used as a measure of " detox fying capacity " , some other tests were applied a well Yet the picture presented by all this detail confused, if not chaotic A not very successfu attempt has been made to classify the cases accordin to the histological changes in the marrow It possible that use of the dry-smear sternal-punctur technique, adopted by several hæmatologists wit encouraging results, might have made this classifica tion more precise , but it is clear that pathologica changes in the bone-marrow are only part of the story Discussion of the relative value of all this evidence must still be left to the expert, but it is useful to see what impressions have been gathered about the ætiology of these cases and what practical experience has taught about their management

[1] Israels M C G and Wilkinson, J F *Quart J Med* 1936, 5, 6
[2] *Ibid*, 1940 9, 163
[3] Rhoads, C P Symposium on the blood and blood formin organs University of Wisconsin, Madison 1939, p 31
[4] Bomford, R R and Rhoads *Quart J Med* 1941, 10, 175 and 23

Rhoads is struck by the resemblance between the refractory anæmias and those anæmias whose course is also independent of treatment, which are known to be due to exposure to potentially hæmotoxic aromatic hydrocarbons, and included in the reported series are 34 cases of refractory anæmia in which the patient had been exposed to benzol paraphenylenediamine (a hair-dye), analgesics like pyramidon and phenacetin, and some other similar substances He also recalled that somewhat similar anæmias had been experimentally produced in animals by substances like indol and œstrin Only a few of the people exposed to these hæmotoxins develop refractory anæmia and it is therefore necessary to postulate a conditioning factor or state Dietary deficiencies or endocrine disturbances could only be detected in a minority of cases but evidence of liver disturbance or failure of the biochemical mechanisms for detoxicating aromatic hydrocarbons was observed more frequently, an increased rate of hæmolysis was also noted Bomford and Rhoads suggest as a working hypothesis of the ætiology of refractory anæmia a conditioned susceptibility to aromatic hydrocarbons to which the patient has been externally exposed or which are being produced in the body itself in the course of normal metabolism, this susceptibility is associated with a disturbance of liver function and detoxicating mechanisms and with the circulation of hæmolytic substances which not only affect the red blood cells but also their precursors in the bone-marrow This theory is still too tentative to be applied to treatment which consequently remains empirical and unsatisfactory Removal from exposure to toxic substances is an obvious measure and should include the abandonment of all sedative drugs containing aromatic hydrocarbons The diet should be adequate in all respects and supplementing the diet with vitamin-B complex is especially recommended Bunding[5] in a recent German report also supports this measure If sternal puncture shows a megaloblastic marrow it is useful to follow Israels and Wilkinson's recommendation to give liver extract—the more refined forms should be avoided When all this is done the mainstay of treatment is blood-transfusion, which should be repeated as needed since a fair proportion of patients eventually show remissions which may be prolonged and occasionally permanent Careful cross-matching is essential since the severely anæmic patients are particularly liable to post-transfusion reactions Bomford and Rhoads believe that transfusions should be used sparingly and are not in favour of raising the hæmoglobin to 70 or 80%—a procedure which has its supporters[6] especially by the method of giving concentrated red cells[7] Transfusions should be continued however bad the outlook may seem As it may be necessary to sustain one of these patients with other people's blood for months or even years, the outlook is indeed grim both for patient and doctor, and it is not easy to decide how long it is proper to wait for signs of remission

Here then are a group of patients whose blood-picture may resemble treatable anæmias but who in practice prove refractory to the known hæmopoietic drugs Their ætiology is still speculative and their treatment empirical The doctor can at present do little more than note their occurrence and resolve to be cautious in prognosis until the effect of treatment becomes clear No patient should however be diagnosed as primary refractory anæmia until a thorough survey of the known causes of anæmia has been made

HIGH FLYING

A group of Boston workers[1] have again emphasised the difficulties in flying at over 32 000 ft even when oxygen is supplied Oxygen constituting as it does a fifth of the atmosphere exerts at sea-level a pressure of 152 mm Hg, being a fifth of the total atmospheric pressure of 760 mm Although its absorption into the blood depends on its pressure, it is normally absorbed at a pressure nearer 100 than 152 mm Hg This is first because the high water-vapour content of the alveoli cuts down the space available for the remaining atmospheric gases and reduces their total pressure from 760 to about 710 mm Hg and secondly because whereas in air oxygen would account for 142 of the 710 mm, so much of it has been exchanged in the lungs for carbon dioxide that the remainder exerts little more than 100 mm pressure Up to a point, diminished entry of oxygen into the blood causes no symptoms the acute discomfort of breath-holding is due entirely to the rising alveolar pressure of carbon dioxide, to which the body is extremely sensitive At low atmospheric pressure if pulmonary ventilation remained unchanged two physical conditions would control the gaseous exchange in the alveoli alveolar air would still be saturated with water vapour which exerting the same pressure as before would account for a greater proportion of the total pressure, and the residual pressure would be divided between carbon dioxide, oxygen and nitrogen in the usual alveolar proportions, each of their pressures being reduced In practice the sensitivity of the body to CO_2 intervenes The diminished alveolar pressure of this gas allows it to escape more readily from the blood so reducing the urge to breathe that CO_2 accumulates in the alveoli at the expense of oxygen In rapid ascents this may lead to the insidious and disastrous results of anoxia In ascents occupying days acclimatisation occurs the control of breathing being switched from the CO_2-sensitive to an oxygen-deficiency-sensitive mechanism This ensures sufficient hyperpnœa to keep the alveolar oxygen pressure as high as it will go, though CO_2 is of course, lost, and alkali is excreted in the urine to keep the pH of the blood constant The obvious way to avert anoxia in rapid ascents is to replace the nitrogen of the inspired air with oxygen, so that no matter how much room is taken up in the lungs by retained CO_2, sufficient oxygen is also present to exert an adequate pressure on the blood At 19 000 ft when the atmospheric pressure has gone down to 360 mm Hg nearly half the air breathed must consist of oxygen if the pressure of this gas in the alveoli is to reach the normal 100 mm Hg It has been suggested that even if this is achieved—so that there should be no stimulus to, or reason for, over breathing—there is excessive elimination of CO_2 This is not confirmed by Butler and his colleagues, who working with decompression chambers find that if the alveolar oxygen pressure is kept normal the CO_2 pressure also remains normal and there is no increase in the alkalinity of the urine They did find however that rapid reductions of atmospheric pressure to 250 mm Hg or less might give rise to symptoms resembling those of anoxia, though they were not due to this They attributed these symptoms to liberation of nitrogen or water-vapour bubbles in the tissues—to the same kind of thing, in fact, as occurs in the rapid decompression of divers

At over 32,000 ft purely physical considerations begin to determine the limit of performance Total atmospheric pressure is now only about 200 mm Hg, of which only 152 mm are available in the lungs after deducting water-vapour pressure Thus even if pure oxygen is breathed the maintenance of a normal CO_2 pressure of 40 mm Hg leaves just sufficient pressure of oxygen to saturate the blood Above this height, pressure of oxygen inexorably diminishes, though at 40,000 ft it is theoretically still sufficient to allow an 88% saturation of the blood But animals exposed to such pressures of pure oxygen die, and Armstrong[2] regarded 30,000 feet as the practical limit of safety Butler and his colleagues point out another hazard when the nitrogen of the air is replaced by oxygen even at low pressure—that of fire, but in civil aviation the deciding factor in altitude is more likely to be the well-known effect of differences in pressure between the atmosphere and the middle ear It seems that the multiple difficulties associated with very high flight can be overcome satisfactorily only by closed-cabin aircraft in which the atmospheric pressure is something like normal

Meanwhile attention must be paid to favourable idiosyncrasies which may account for some aviators having a resistance to altitude slightly above the average On the basis of the remarkable survival of thyroidectomised rats at a barometric pressure sufficiently low to kill all normal rats, Barach, Eckman and Molomut[3] suggest that a low metabolic rate may be an advantage It is doubtful if they would have obtained such favourable results if they had reduced the temperature as well as the pressure of their exposure chamber so as to imitate more closely the conditions met in flying Their less sensational finding[4] that twenty cigarettes bind an average of 5 7% of the total O_2-combining power of blood to CO may in practice prove more important, and we await with interest their projected experiments in which these findings are to be correlated with the actual demand of the tissues for oxygen

The directors of the Cooperative Wholesale Society Ltd ask us to state that all national wheatmeal made by their mills is produced strictly in accordance with the specification laid down by the Medical Research Council The average fibre content of their product, as revealed by analysis over a long period, is less than 0 8%

Annotations

THE PROPER SCHOOL MEAL

Anyone disheartened with the slow rate of progress applied nutritional science in this country will be encouraged by the latest circular (No 1571) of the Board of Education which sets out not only the principles upon which the provision of school meals should be based but also the types and quantities of foods which are necessary The first principle is that in planning a midday meal for school-children it is essential to consider the probable defects of their home diet This is almost certainly lacking in first class protein, fat, calcium, iron and the vitamins, and the board aim at making good these deficiencies, at any rate in part For a dinner to provide about 1000 calories they recommend 20–25 g of first class protein, 30 g of fat and suitable amounts of vitamins and minerals The second principle is that the nutritive value and not the low cost of the meal should be the first consideration and the board deplore that there "still are some instances where the authorised *allowances of food have not been bought in full owing to a* well-meant but mistaken effort to keep the price of the school dinner very low or even to make a profit for sports funds " Economy, they insist, should be studied "not by reducing the quantity or the quality of the food and staving off hunger with liquids such as soup, but by avoiding waste, by skilled buying and by good cooking The board might well borrow a leaf from the bulletin of the Children's Nutrition Council and add "by studying child likes and dislikes, by working within their ambit, and by subtly training the child to eat unwanted but nutritious foods "[1] The low table wastage at Christ's Hospital[2]—less than 1% compared with the average 10%—was achieved by these methods A third principle is that no child should go without a nutritious midday meal because his parents cannot contribute to the cost "If it is found that some of the parents cannot pay the full cost of the food the remedy is not to give a poorer meal, but to adjust the income scales so as to provide for meals on part payment, as well as for free meals "

And lastly there is the principle that cost of supervision and preparation of the meals must not be scamped, for the provision of "balanced meals" needs intelligence and training, and so costs more "A skilled organising and catering staff is therefore essential and there is no true economy in offering wages too low to attract competent cooks and helpers" We prefer to ask for dietitians (or nutritionists as Americans call them)—though as yet we have trained far too few in this country to meet the demand—for there will be difficulty in interpreting the board's wishes from the lists given as a guide to the quantities of the main foods to be used Taking the full range of foods and using the quantity of dried milk allowed, the diet works out at 17 g of first class protein 400 mg of calcium, 4 3 mg of iron, 900 I.U (and possibly more) of vitamin A, 20+I U of vitamin D, 0 6 mg of vitamin B_1 and 19 mg of vitamin C per meal This is a satisfactory diet, though the iron is low But if liquid milk is used instead of dried milk in cooking it appears as though the first class protein and the calcium will be considerably lower, because the liquid milk allowed is by no means equal to the alternative amount of dried milk Again it is notoriously difficult to persuade children to eat carrots, cabbage and green vegetables, and it is a temptation to the cook to omit them from the diet and give the children those things which they will eat Moreover, unless the cook is dietetically minded the menus will tend to become more and more what she herself likes to eat There must therefore be a skilled dietetic supervision of the menus and of the children's likes and islikes and attempts should be made, as in Aberdeen,[1] to induce them to eat unaccustomed but protective foods. The board have recognised that children must be proportionately better fed than adults, but to put this principle into practice they will need dietitians as well as books.

ALLERGIC EPILEPSY

EPILEPSY, with its recurring fits, is an obvious candidate for the allergic pigeonhole, and the papers that have been written about the wisdom of this course would themselves fill a good few pigeonholes. A study of these papers induces something of the state of bewilderment produced by a search for truth about current events in war-time. A valiant attack on the subject has recently been made by D. C. Dewar,[3] though one would hardly expect that the patients he investigated—chronic idiopathic epileptics in a mental hospital—would provide the most promising field. Strong prima facie evidence of a connexion between epilepsy and allergy was afforded by his finding that two-thirds of these patients (four times the proportion in a control group) gave either a personal or a family history of allergy, but he does not specify what conditions constitute allergy. To intradermal skin tests he found that 58% of his epileptics, as against 4% of controls, were positive, many of the former showing multiple sensitivity. Offending foods having been eliminated from their diet, twelve epileptics were treated by specific desensitisation. The intramuscular route was adopted and in half the cases an attempt made to control dosage and avoid the risk of oversensitisation, and consequent increase of fits, by repeated eosinophil counts. Sensitivity tests made at the conclusion of the course of injections and again three months later showed that desensitisation had been achieved in most of the cases. A year later Dewar found that there had been a definite reduction, in one case a most dramatic reduction, in fit incidence in seven of the twelve patients, and the decrease in fits as well as mental improvement, can be fairly well correlated with the degree of desensitisation. The value of the paper is greatly enhanced by full details of the techniques employed. The treatment of epilepsy as an allergic manifestation is of necessity a painstaking and laborious process, and brilliant results are likely to remain exceptional. Anyone who wishes to try it out should make a detailed study of this paper before he starts.

PHYSICAL TYPE IN PNEUMOCONIOSIS

PEOPLE who are exposed to apparently equal risks from pneumoconiosis-producing dusts do not, of course, all succumb to those hazards. One differentiating factor between the affected and the unaffected might lie in constitutional type and indeed this view has not only been put forward but to some extent acted on in selecting entrants to the mining industry. The belief is that by excluding certain anthropometric types the incidence of pneumoconiosis, or of pneumoconiosis complicated by tuberculosis, could be reduced. Statistical data have so far been lacking and Aslett, Hart, Martin and Russell[4] give but little encouragement to the hypothesis. Their material is derived from part of the wide survey which has been made in South Wales under the direction of the industrial pulmonary diseases committee of the Medical Research Council. Measurements of 540 workers at an anthracite colliery were available and could be divided into groups of unaffected workers and those with pneumoconiosis of varying degrees. They comprise standing and sitting heights, weight, circumference, anteroposterior diameter, lateral diameter and length of the chest, and radiological measurements. From these various indices have been calculated as well, and comparison is made between the normals and the cases of reticulation, nodulation and major consolidation. The general result of this careful study is that there is little difference in bodily make-up between the affected and the unaffected. For instance the average height differs negligibly so that there is no reason to think that the normals tend to be the "short and tubby" pyknics and the affected the "tall and thin" asthenics. While one or two of the indices—e.g., height/chest lateral diameter—suggest a slight association between type and reaction to the environment there is clearly no differentiation sufficiently well marked to permit the identification of the future pneumoconiotic case. To avoid recruiting those particularly susceptible to the dust hazard—if they really exist—is, it goes without saying, most desirable. There is, unfortunately, no evidence here that such guidance can be usefully based on bodily measurements.

PARALYSED PAPER

PAPER is badly needed for munitions of war but most of us would rather do without a meal than give up a book or a packet of letters. It must be done, and done now as our own contribution to the cause. And there is an added reason for a profession which has its own books and journals. The medical journals are feeling the pinch of paper shortage and if this shortage becomes worse progress in medicine and particularly the dissemination of new knowledge will be held up by difficulty in getting new work published. Doctors themselves can do much to avert this threat for we are among the larger users of paper and run lawyers a bad second as hoarders of it. Most of the compound celluloses from which our paper is made come from abroad and are not likely to be plentiful while war lasts, but fortunately paper like currency, can circulate, and our aim must be to keep it circulating. The textbooks of our student days now of historical interest only, the ledgers of thirty years ago the incomplete and unbound sets of journals which we could not consult even if we would these with the old letters and out-of-date receipts which every literate household possesses must go to the salvage authorities. A Sunday afternoon of selective rummaging will mean less dust in the home, more room in the attic and new facts for old.

NOT SO STERILE WATER

MOST hospital bacteriologists are familiar with the non-purulent spinal fluid which on receipt at the laboratory yields a small gram-negative bacillus or other indeterminate organism. They have usually suspected these organisms to be contaminants from the so called sterile water or saline in which the spinal needle is placed after boiling or with which it is rinsed after sterilisation in an antiseptic fluid. They will therefore be grateful to Professor and Mrs Wilson Smith for showing by systematic investigation of 223 specimens of cerebrospinal fluid and 11 samples of "sterile water" used for rinsing the spinal needles that two-fifths of the spinal fluids were contaminated and that more than a third of the contaminants probably came from the sterile water. Besides the gram-negative water bacillus, which grows best in peptone water at room-temperature, *Staphylococcus albus*, coliform bacilli, diphtheroids, non-hæmolytic streptococci and other organisms were encountered, suggesting that spinal puncture is often carried out without regard to the ordinary rules of asepsis. The resulting contamination is irritating enough to the bacteriologist and may even lead the unwary astray, but the matter becomes much more serious when the same laxity of technique is used in the injection of spinal anæsthetics. Barrie[1] has reported 11 cases of meningitis with one death among 96 consecutive patients operated on under spinal anæsthesia in one theatre. The meningeal infection which was seldom severe, was characterised by the abrupt onset of headache 7–10 days after operation, usually associated with drowsiness, irritability, photophobia

phapyridine was started In most cases the drug given by mouth though in a few instances when the nt was desperately ill, was vomiting or was so ly distended that all administration by mouth had be discontinued the sodium salt was given intra-ously The daily dosage used was approximately 1½ per lb body-weight, divided into six doses at 4 hour rvals As a general rule half the 24 hour dose was n as the initial dose The drug was given as a powder pended in water, and the average total dose was gr 75 drug was continued as a rule for about 48 hours r the temperature had returned to normal For group of 89 infants of whom half received sulphapyri-t, it was found that in those treated by chemo rapy the temperature subsided more quickly, reaching mal on an average by the fourth day as compared h the seventh day among the controls The length of pital stay, the total duration of illness and the dence of extension of the pneumonia were all favour r influenced in those treated with sulphapyridine, ough, this group included the most seriously ill nts For the larger series of 200 treated infants the ity rate was 10% Thus a reduction to less than a d of what it used to be has been achieved in infants e the introduction of sulphapyridine, and in addition course of disease has been shortened and the incidence spread and complications—notably empyema—atly decreased Reactions to the drug are less uent among infants than among adults Vomiting remarkably rare considering the ease with which vomit, and this means that good sized doses can be given Other methods of treatment have naturally not been neglected The use of oxygen and prompt measures to deal with abdominal distension (parenteral fluids, rectal tube and continuous gastric aspiration) have been employed as hitherto Specific antipneumococcal serum has been used in some instances when indicated by typing No exactly comparable series has been published in the British Isles but it is note worthy that the fatality rate from bronchopneumonia reported[7] by C J McSweeney of Dublin was reduced in the under 5 group from 30% in 1938 to 10% in 1939, the first sulphapyridine year—the same figure as was achieved in Chicago

NIGHT-BLINDNESS

THE Finns are now said to be getting very short of food, and for some time the authorities there have been anxious about the shortage of sources of vitamin A and carotene The other Scandinavian countries and no doubt the Finns as well, are normally large consumers of dairy produce and eat few vegetables so that they rely almost entirely on animal fats for their vitamin A Nylund[8] made a study of night blindness in Finland in October and November, 1940, with a view to determining whether there had been any increase in vitamin-A deficiency since the war began He compared his findings in 31 students with those in 82 students examined two years earlier Of the 82 seen in 1938 79% showed normal adaptation, 9% were night blind and 12% were borderline, in the 1940 group only 48% had normal adaptation, 29% were night blind and 23% borderline He also compared his findings in 40 pregnant and nursing women (in whom the vitamin-A requirements are known to be high) with those in a similar series tested in 1938 Here again there was a falling off in dark adaptation—from normal adaptation in 95% and night-blindness in 5% the standard had fallen by 1940 to normal adaptation in 65% and night blindness in 25%, with 10% on the borderline Rationing of dairy products began two months before the 1940 tests were made, the daily amounts allowed being butter 25 g (⅞ oz), cream containing 10% fat 50 g (1¾ oz) and milk 200 g (7 oz) The average daily diet at that time was estimated as containing liver 3 g ($\frac{1}{10}$ oz), meat 150 g (5¼ oz), carrots and other vegetables 5 g (⅙ oz) On this basis the average daily intake was assessed at 1055–1280 I U of vitamin A, plus 455–1585 μg of carotene This was certainly insufficient, and Nylund urged an increased consumption of carrots, beans and spinach, with extra liver once a week Pregnant and nursing women had been allowed larger rations, receiving daily 40 g (1⅖ oz) of butter, 50 g (1¾ oz) of cream and 600 g (21 oz) of milk Their average daily diet thus contained 1870–2230 I U of vitamin A and 750–1960 μg of carotene Night blindness did not develop on this diet and it was found that dark-adaptation was fully normal if a minimum of 2000 I U of the vitamin was supplied daily

Other workers have put vitamin-A requirements higher, and it is usual now to express these in terms of body-weight A distinction must be made also between the optimum daily intake and the minimum required to prevent dietary night-blindness in otherwise normal people Thus for an adult man the optimum is considered by Booher[9] to be 40–60 I U per kg body-weight daily, or 3000–4000 I U for a man of 150 lb, the minimum protective intake for a man is 20–30 I U per kg daily, or 1500–2000 I U More accurate work is required, however before any definite figure can be universally accepted The vitamin-A needs of the newborn child are thought to be covered by the vitamin-A content of colostrum and breast milk, provided the intake of the mother is adequate The most reliable estimate of the daily requirement of pregnant and lactating women is 5000–6000 I U

Two retinal mechanisms are concerned in dark-adaptation During the first 7 minutes the photopic mechanism of the cones is engaged Subsequently the scotopic adaptation of the rods comes into play and continues slowly for several hours More than 95% of dark-adaptation, however, is complete after 30–40 min in darkness Vitamin A is an essential constituent of visual purple, which is found only in the rods but it appears also to be essential for the complete dark-adaptation of the cones In many cases of experimentally induced night blindness impairment of dark-adaptation begins on the first day of the vitamin-A deficient diet and may be significant within a week In these cases it has often been shown that vitamin-A brings about a rapid improvement, followed by a more gradual process of complete recovery, so that normal dark-adaptation may take longer to regain than to lose It has been suggested that recovery may be hastened by adding riboflavin and ascorbic acid to the diet, in addition to a supplement of vitamin A To obtain the most prompt and complete recovery, massive doses (100,000–300,000 I U daily) have been recommended by some workers, others have obtained the same result with doses as low as 10,000 I U

MR PERCY FLEMMING, consulting ophthalmic surgeon to University College Hospital, died at his home at Upper Basildon, on Dec 19, at the age of 78

AN editorial board has been set up under the chairmanship of the President of the Board of Education to direct the compilation of a medical history of the war The Fighting Services, the Ministry of Health the Department of Health for Scotland, the Medical Research Council and the War Cabinet secretariat, will be represented and Sir ARTHUR MACNALTY has been appointed editor-in-chief

---

MEDICAL HONOURS —The military cross has been awarded to Captain Leonard Bapty, M B Aberd, R A M C, and the R N V R officers decoration to Surgeon Commander D C Wilson, F R C P E and neck rigidity The cerebrospinal fluid, examined in 6 cases, showed evidence of a mild purulent meningitis It seems pertinent to ask whether the severe headache which may follow spinal anæsthesia is not sometimes due to meninges infected in this way In the induction of spinal anæsthesia, the anæsthetist should wear sterile gloves, the skin of the patient s back should be covered with a visible antiseptic like iodine and the spinal needle should either be boiled and put in a dry sterile container or be previously sterilised in an autoclave or hot air oven in an appropriate closed container Boiled water or saline used repeatedly from a Winchester or other large bottle for rinsing or immersing sterile instruments and needles is very liable to become infected as Bigger and Nelson[2] have shown, and this practice, all too common in hospitals, cannot be too strongly deprecated Indeed, the need for a bacteriological control of hospital methods becomes ever more apparent

TRAUMATIC ARTERIAL SPASM

THE local constriction of a vessel wall in response to trauma is a well-recognised phenomenon, apparent even in the injection of varicose veins Operations on arteries are impeded by this spasm, and it has long been known that constriction of the severed ends may be sufficient to arrest hæmorrhage in severe arterial damage Nevertheless the importance of a local vasoconstrictor reflex in jeopardising the vitality of a limb which has been injured is not very well recognised Last year Griffiths[3] cited traumatic arterial spasm as the cause of Volkmann's ischæmic contracture, and recently Cohen[4] has brought together clinical reports of a variety of cases illustrating effects produced by spasm of the intact vessel as a result of injury, and the type of treatment that can be applied with hope of success He shows that simple exposure of the artery at the site of injury may be sufficient to arrest the spasm, though there is as yet no explanation of this remarkable fact In his first case the injury was caused by a splinter of glass or of a bomb—it was not known which did the damage—passing through the arm just below the elbow-joint The radial and ulnar pulses were absent, though they were easily palpable on the opposite side There was a musculospiral nerve palsy At operation six hours after admission it was found that the missile had just skirted the joint capsule, the nerve was contused but intact, and the biceps tendon was almost completely severed The brachial artery was not pulsating, and was surrounded by a network of soft clot For a distance of about 2 cm proximal to the origin of the radial artery a fine blue stippling indicated bruising A tourniquet was applied, the artery was freed from the clot and from a fine areolar tissue and pulsation returned as the tourniquet was released The pulse after operation remained normal and the limb recovered

Apart from penetrating wounds, other types of trauma which may be associated with arterial spasm are the application of a tourniquet (especially dangerous on the arm), fracture of a bone in the neighbourhood of a large vessel, application of plaster of paris to a limb, and skeletal traction to the lower leg on a Bohler's frame with the knee flexed In this method of traction the knee forms the fixed point from which the traction acts, and the popliteal artery may be injured Cohen gives examples of all these types of injury in which ischæmia resulted in the loss of the limb He quotes Trueta's experience of the danger of tourniquets in the Spanish war Towards the end of the war the Spanish surgeons used them only as very temporary expedients Recognition of the danger of arterial spasm in fractures near large vessels should make the surgeon wary of applying closed plaster in the early stages It is probable that, with badly contused limbs, it is better to method of slinging in a Thomas splint with care not to compress at the flexures E impaired circulation will then be obtained in time surgeon to operate with success, and plaster applied after the first two or three days have elapsed the danger of ischæmia is over If ischæmia sequelæ may be gangrene of the limb nec amputation, gas gangrene infection of the d and deoxygenated tissues, with danger to the life, or Volkmann's ischæmic contracture of the muscle ending in gross deformity and disability It is n enough to relieve the cause of the trauma—to remove plaster or tourniquet or to release traction The surgeo must bear in mind that the spasm may continue, an if it does he must explore until he finds the spastic arte He should examine it gently and look for evidence damage, careful exposure and lavage with warm sal may cause it to dilate but if these measures fail he ca try the effect of intravenous injection of papaverine If there is a localised trauma, such as a hæmatoma, may be wise to follow the practice of Leriche[5] an excise a few centimetres of the damaged vessel Lerich was concerned to restore the collateral circulation, [illegible] theory being that the reflex starting in the wall of [illegible] main vessel, caused vasoconstriction in the collate This point is not mentioned by Cohen, but it de serious attention because the hope of restorin collateral circulation is almost the only consider which would persuade a surgeon to undertake [illegible] local arteriectomy

Other methods, short of operation, which have be used successfully in treating ischæmia are paravertebra injections of procaine and spinal anæsthesia For the upper limb, Cohen suggests that brachial plexus block anæsthesia is worthy of trial Papaverine might also be tried without exploration, though it is probably more useful when the exposed vessel remains obstinately contracted Exploration to have the best chance of success, must be carried out early—within six hours, in Cohen's opinion Pain may not be serious it seems to arise from continued ischæmia of the muscles and not directly in the spastic vessel In most cases it is as well not to suture the wound Closure of the damaged tissues may lead to compression, and in any case adds a little to the risk of gas gangrene

SULPHONAMIDES AND INFANTILE PNEUMONIA

THE mortality from pneumonia in childhood has always been greatest in infancy and the experience recorded by J Greengard W B Raycraft and W G Motel[6] in the children's division of Cook County Hospital of the effect of the sulphonamides on this mortality is therefore welcome In 1937 and 1938, before chemotherapy was used, the fatality rates were 32% and 31% The infants, all under 1 year, were drawn from essentially the same group and were treated by the same medical personnel and with the same therapeutic measures other than specific chemotherapy as the 1940 series which is now reported It was originally planned to give specific chemotherapy to alternate infants but it was found after this procedure had been continued for some months that "the natural human reactions" on the part of house physicians led to the use of the sulphonamides for the most seriously ill infants This method was therefore discontinued after half a series of 89 infants had received sulphapyridine, and a group of 200 infants were all treated with this drug Bacteriological control was effected in every case by taking a laryngeal swab through a Flagg direct laryngoscope The commonest types of pneumococci were type XIV in 36 cases, type XIX in 31 cases, type VI in 25 cases, and type VII in 18 cases As soon as a specimen of sputum had been obtained sulphapyridine was started. In most cases the drug was given by mouth though in a few instances when the patient was desperately ill, was vomiting or was so badly distended that all administration by mouth had to be discontinued the sodium salt was given intravenously. The daily dosage used was approximately 1½ per lb body-weight divided into six doses at 4 hour intervals. As a general rule half the 24 hour dose was given as the initial dose. The drug was given as a powder suspended in water and the average total dose was gr 75. The drug was continued as a rule for about 48 hours after the temperature had returned to normal. For the group of 89 infants of whom half received sulphapyridine, it was found that in those treated by chemotherapy the temperature subsided more quickly reaching normal on an average by the fourth day as compared with the seventh day among the controls. The length of hospital stay the total duration of illness and the incidence of extension of the pneumonia were all favourably influenced in those treated with sulphapyridine although this group included the most seriously ill infants. For the larger series of 200 treated infants the fatality rate was 10%. Thus a reduction to less than a third of what it used to be has been achieved in infants since the introduction of sulphapyridine, and in addition the course of disease has been shortened and the incidence of spread and complications—notably empyema—greatly decreased. Reactions to the drug are less frequent among infants than among adults. Vomiting is remarkably rare considering the ease with which infants vomit, and this means that good-sized doses can be given. Other methods of treatment have naturally not been neglected. The use of oxygen and prompt measures to deal with abdominal distension (parenteral fluids rectal tube and continuous gastric aspiration) have been employed as hitherto. Specific antipneumococcal serum has been used in some instances when indicated by typing. No exactly comparable work has been published in the British Isles but it is noteworthy that the fatality-rate from bronchopneumonia reported[7] by C J McSweeney of Dublin was reduced in the under-5 group from 30% in 1938 to 10% in 1939, the first sulphapyridine year—the same figure as was achieved in Chicago.

NIGHT-BLINDNESS

The Finns are now said to be getting very short of food and for some time the authorities there have been anxious about the shortage of sources of vitamin A and carotene. The other Scandinavian countries and no doubt the Finns as well, are normally large consumers of dairy produce and eat few vegetables so that they rely almost entirely on animal fats for their vitamin A. Nylund[8] made a study of night-blindness in Finland in October and November, 1940 with a view to determining whether there had been any increase in vitamin-A deficiency since the war began. He compared his findings in 31 students with those in 82 students examined two years earlier. Of the 82 seen in 1938 79% showed normal adaptation, 9% were night-blind and 12% were borderline, in the 1940 group only 48% had normal adaptation, 29% were night-blind and 23% borderline. He also compared his findings in 40 pregnant and nursing women (in whom the vitamin-A requirements are known to be high) with those in a similar series tested in 1938. Here again there was a falling off in dark-adaptation—from normal adaptation in 95% and night-blindness in 5% the standard had fallen by 1940 to normal adaptation in 65% and night blindness in 25%, with 10% on the borderline. Rationing of dairy products began two months before the 1940 tests were made, the daily amounts allowed being butter 25 g (⅞ oz), cream containing 10% fat 50 g (1¾ oz) and milk 200 g (7 oz). The average daily diet at that time was estimated as containing liver 3 g (1/10 oz), meat 150 g (5¼ oz) carrots and other vegetables 5 g (⅙ oz). On this basis the average daily intake was assessed at 1055–1280 I U of vitamin A plus 455–1585 μg of carotene. This was certainly insufficient and Nylund urged an increased consumption of carrots beans and spinach with extra liver once a week. Pregnant and nursing women had been allowed larger rations receiving daily 40 g (1⅖ oz) of butter 50 g (1¾ oz) of cream and 600 g (21 oz) of milk. Their average daily diet thus contained 1870–2230 I U of vitamin A and 750–1960 μg of carotene. Night-blindness did not develop on this diet and it was found that dark-adaptation was fully normal if a minimum of 2000 I U of the vitamin was supplied daily.

Other workers have put vitamin-A requirements higher and it is usual now to express these in terms of body-weight. A distinction must be made also between the optimum daily intake and the minimum required to prevent dietary night-blindness in otherwise normal people. Thus for an adult man the optimum is considered by Booher[9] to be 40–60 I U per kg body-weight daily, or 3000–4000 I U for a man of 150 lb. the minimum protective intake for a man is 20–30 I U per kg daily, or 1500–2000 I U. More accurate work is required, however before any definite figure can be universally accepted. The vitamin-A needs of the newborn child are thought to be covered by the vitamin-A content of colostrum and breast milk provided the intake of the mother is adequate. The most reliable estimate of the daily requirement of pregnant and lactating women is 5000–6000 I U.

Two retinal mechanisms are concerned in dark-adaptation. During the first 7 minutes the photopic mechanism of the cones is engaged. Subsequently the scotopic adaptation of the rods comes into play and continues slowly for several hours. More than 95% of dark-adaptation however is complete after 30–40 min in darkness. Vitamin A is an essential constituent of visual purple which is found only in the rods but it appears also to be essential for the complete dark-adaptation of the cones. In many cases of experimentally induced night blindness impairment of dark-adaptation begins on the first day of the vitamin-A-deficient diet and may be significant within a week. In these cases it has often been shown that vitamin-A brings about a rapid improvement followed by a more gradual process of complete recovery so that normal dark-adaptation may take longer to regain than to lose. It has been suggested that recovery may be hastened by adding riboflavin and ascorbic acid to the diet in addition to a supplement of vitamin A. To obtain the most prompt and complete recovery massive doses (100 000–300 000 I U daily) have been recommended by some workers, others have obtained the same result with doses as low as 10,000 I U.

Mr Percy Flemming consulting ophthalmic surgeon to University College Hospital died at his home at Upper Basildon on Dec 19 at the age of 78.

An editorial board has been set up under the chairmanship of the President of the Board of Education to direct the compilation of a medical history of the war. The Fighting Services the Ministry of Health the Department of Health for Scotland, the Medical Research Council and the War Cabinet secretariat will be represented and Sir Arthur MacNalty has been appointed editor-in-chief.

itten We might then at last get a textbook which as readable and it could be kept constantly up to date y replacing obsolete information with new leaves This extbook—or rather the series of them to cover all the ecial subjects—should be sent free to all members of he medical profession including students and the upplements would also be free Though this would be n added burden on the public purse it would be in a ood cause An organisation for disseminating informa-on on the latest methods of treating air-raid casualties lready exists The E M S sends round circulars on fficial methods of treatment and is even collecting nformation on some subjects An extension of this rinciple to the whole of medical practice could hardly e thought objectionable

* * *

Let us then demand facilities for the proper organisa-ion of research for assuring the research worker a reasonable living for leading him to the problems which most urgently require solution for preventing him from ngaging on redundant work for providing him with an dequate resume of all that is known about his chosen subject and, most important of all for getting the knowledge as quickly as possible to those whose job it is to use it We need an organisation which as H G Wells puts it accumulates sorts keeps in order and renders available everything that is known '

PALESTINE

MORTALITY AND SICKNESS AMONG INFANTS

THE infant mortality in the past ten years has been analysed in the July issue of *Hadassah* the bulletin of the Jerusalem University Hospital The deaths have been grouped according to the various races found in Palestine and it is encouraging to find that the rate has fallen in all sections of the community Thus over the period 1931–40 the rate has fallen from 186 per 1000 to 147 among Arabs from 133 to 107 among Christians and from 81 to 59 among Jews The infant death-rate is highest between April and September the Palestinian summer months Among Arab infants the summer rate is double that in winter and among Jews half as much again as the winter rate The commonest recorded causes of death are congenital debility diarrhœa and enteritis and bronchopneumonia Bograchow of the children s department at Tel Aviv in an account of his experience with infantile diarrhœa during 1938–40 says that on the whole the disease affects older infants in Palestine than it does in Europe because almost all Jewish mothers breast-feed their infants who are thus safeguarded against infection carried by cow s or goat's milk Nevertheless the social status of the family and the nutrition of the infant are important in ætiology and prognosis Thus infantile diarrhœa is very common among the poorer Jewish families Nutritional disorders are also common and often associated with qualitative or quantitative hunger He mentions a toxic form of infantile dysentery with a fatality of 100%

POISONOUS BITES AND STINGS

J Seide of Jerusalem writing in *Harefuah*, reviews the poisonous fauna of Palestine These include the jelly fish, *Rhizostoma pulmo* and *Aurelio aurita* and the sea anemone stings from which give rise to toxic skin eruptions The bite of the centipede *Scolopendra cingulata* causes pain and swelling but is otherwise harmless Spiders of the genus *latrodectus* are highly poisonous and a sting from one may endanger life in a child *Tarantula albofasciata* is less poisonous There are six different species of scorpion in Palestine all of them poisonous The commonest is the yellow *Buthus quinquestriatus* which gives an extremely painful sting causing local inflammation and sometimes constitutional disturbance though Seide had never seen a death from such a sting Bees wasps and hornets sting like their kin elsewhere and bites from ants are negligible Several species of poisonous fish cause trouble to fishermen, including species of scorpæna and trachinus The venomous snakes found are mostly vipers the oriental form of the Levant viper being the most common in inhabited parts of the country ; its bite may cause death and prognosis depends chiefly on the promptness with which antitoxin can be given Of 23 cases treated in hospital 3 were fatal Bites from *Vipera lebetina* are discussed more fully by Lefkovitz in a separate paper These are becoming commonest during the hotter months The victim develops local and general signs among which circulatory disturbances are prominent indeed vasomotor instability often persists for years after the bite At the time of the injury œdema and hæmorrhages are common Experiments on frogs suggest that the toxin attacks the vascular endothelium causing progressive engorgement of the peripheral vessels ; the condition spreads from the region of the bite The patient develops hypotension low temperature and myocardial failure with collapse, and may die from circulatory failure Treatment at present recommended is ligation of the affected limb and injection of serum

PRECAUTIONS AGAINST MALARIA

Malaria is increasing in some of the northern districts The health department of the Jewish agency and the university appointed a committee of inquiry under the chairmanship of Professor Mar which reported some months ago (*Hadassah* March 1941) The committee advised that the tents and huts of the colonists should be provided with mosquito-nets and that specially constructed doors should be supplied to the huts These recommendations are being carried out and the colonists are being instructed in keeping their irrigation canals clean and free from plants so as to discourage the breeding of the larvæ

MILK FOR INVALIDS

UNDER the Ministry of Food s milk-supply scheme priority-supplies of liquid milk are allowed to certain invalids against a certificate given by a medical practitioner The conditions qualifying for these special supplies are now specified in a list drawn up by the ministry's medical advisers and made public on Dec 11, as follows

Active tuberculosis of all types ,
Silicosis
Affection of the mouth, throat or gullet or organic nervous disorder causing interference with swallowing
Gastric, duodenal or anastomotic ulcer
Illness characterised by high and prolonged fever ,
Post operative conditions after major operations ,
Active workers, including domestic workers during an illness which temporarily incapacitates them for work
Sick children not attending school
Dyspepsia due to conditions other than ulceration of the stomach or duodenum ,
Colitis , Diabetes mellitus ,
Thyrotoxicosis Nephritis
Hyperemesis gravidarum , chorea of pregnancy , acute yellow atrophy occurring during pregnancy , albuminuria of pregnancy , eclampsia , which are of sufficient severity to entail total confinement to bed

These diseases and illnesses are the only conditions for which special supplies of milk to invalids may be authorised by a medical practitioner The quantity of milk allowed is at the discretion of the doctor subject to a scale prescribed by the Ministry of Food

FUTURE OF MEDICAL RESEARCH

W. W. WALTHER, M.B. LOND.
DIRECTOR OF PATHOLOGY, QUEEN MARY'S HOSPITAL FOR THE EAST END

THERE is some justification for saying that we are living in the Golden Age of Medicine for at no previous time have there been so many advances in such a short space. For example the sulphonamide group of drugs alone have revolutionised the treatment of many common conditions. And yet there is still much room for improvement in the organisation which makes these discoveries possible. Research does not consist simply of working out and publishing the results of an original idea. Much time must be spent in reading through the literature of work already done on the subject, a task which may involve one in many strange languages, only to find perhaps at the end of many weeks of labour, that somebody else has already worked out the same problem but has somehow failed to get immediate recognition.

In spite of the enormous volume of research which is published little of it ever finds its way into general use, partly because much of it remains unverified and partly because it is simply not noticed. This does not sound at all like a golden age but the statement is easily supported by facts. For example, the original suggestion (based on sound observation) that the shock of burns should be treated by transfusion with a protein-containing fluid was made in the middle of last century. Yet this very practical suggestion was overlooked and only rediscovered during the last few years. Presumably nobody noticed it and it therefore failed to get verified. On the other hand some discoveries seem so much to catch the researcher's fancy that a vast and unnecessary amount of redundant work is wasted on one particular subject. An example of this is the spate of literature which followed the first few papers about prontosil and allied drugs. It has been estimated that the number of papers published on this subject is in the region of ten thousand. Now even the most confirmed sceptic would hardly demand such a vast literature to convince him, and many of these papers are based on such a small number of cases that by themselves they would be of little significance. And yet, until an enormous amount of work on any particular subject gets published, the general practitioner does not hear about it unless it concerns some material whose advertisements are pushed under his nose. This is because the busy doctor has little time to wade through (or income to pay for) all of the large number of medical journals which are published today. But there are plenty of would-be contributors to these journals, largely owing to the fact that besides the quest for knowledge and the desire to benefit humanity there is a need to attain personal recognition. A few publications are a great recommendation for a job, with the result that, as Miller[1] says, "We find it necessary to digest an ever-increasing number of half-baked adventures in medical research." Often enough, in the haste occasioned by the desire to be first in the field, the work is scamped. Sometimes this may also be due to lack of facilities to carry out some important detail of the work. General practitioners have few facilities for accurate work or for producing a number of results sufficient to be statistically significant. In this way a large potential army of keen men is immediately robbed of its keenness. Or, if an effort is made, it lacks numerical weight. Yet under skilled guidance individual efforts can often be turned to good account. There is no dearth of subjects for research, but we lack an organisation which can apportion the work to the best advantage. Although many people no doubt prefer to choose their own subject, it is probable that under a competent authority most would be prepared to work at some set problem either singly or as members of a team.

Many believe that research is insufficiently endowed, and point out that the money available is usually only sufficient to support a newly qualified man, without domestic commitments, on a whole-time basis. Now there is no special virtue in whole-time research work, though one may be forced to devote one's whole time to order to do one's own reading. Neither is it certain the newly qualified man, however keen, is the best for research. Admittedly, the ideas are often sup by the head of a department while the actual wor carried out by assistants, but this does not cover should not cover the whole field of research.

The criticism of modern research thus falls three heads—inadequate endowment, lack of orga tion, and a failure to get results embodied in practice reasonable space of time. It is unlikely that the pr endowment of research will increase in the future, and best way out of the difficulty seems to be the devel ment of a part-time arrangement whereby any body paid by the state (and the number now is greater t ever before and likely to be greater still) should b allowed sufficient spare time to do research if the faciliti exist for it. In certain circumstances a definite pri might be offered for the solving of some particul problem. The prize of £10,000 offered by a daily news paper encouraged research into television, with the resul that, before the war, England led the world in this field and has since led it again in radiolocation.

A CENTRAL BUREAU

For the proper organisation of research some respon sible controlling body would have to be set up. This body would be equipped with an adequate library and permanent staff whose duties would include the prepara tion of abstracts of all that is known on particular subjects in any language, so that the intending researcher is saved the trouble of reading a vast amount of lite in order perhaps to clear up one small point. In ad they should be capable of giving up-to-the mi information on any medical subject to any medi practitioner who asks for it, day or night. This loo a formidable task, but, with an efficient card-index an cross-referencing system, a trained staff would soon fin no difficulty in giving rapid answers to questions. Th cost of maintaining such a library would be great, but would be well worth it. H. G. Wells, in his "Shape Things to Come" had such a scheme for the card indexin of all knowledge—the "Memory of Mankind," wit headquarters in Barcelona. All research work, bot current and projected, would have to be registered wit the bureau, which would then be able to prevent anyon from engaging on redundant work. It could als apportion the work to the best advantage, and organis the appropriate team for the rapid solution of speci problems and for the verification of important observa tions in the shortest possible time. Another importan function would be the organisation of teams of gener practitioners, with the use of laboratory facilities, t carry out research on minor ailments which do not usuall find their way to hospital beds. All this could only b done by an official body with wide powers which enjoye the confidence of the whole medical profession. Such body should, of course, be organised internationally, lik the International Labour Office at Geneva, but as th post-war future is impossible to foresee a start should b made here. The tendencies of foreign research shoul be watched and all allied and friendly neutral countri asked to participate in an exchange of medical knowledg

The results obtained would be examined for contr dictions which could be dealt with immediately b repetition, they would then be submitted to statistic analysis and finally written up in collaboration with a editorial staff whose job it would be to compress th material into as small a space as would be consistent wit clarity. An accurate abstract would be prepared at th same time. Important results might well be published full in a separate international journal of researc simultaneously produced in those countries whic participated, and the abstracts would appear in th regular journals.

The rapid dissemination of results important t practitioners would be the last and most important dut of the bureau. As has already been pointed out, owin to the multiplicity of journals, results may never reac the people who would most benefit by them. To correc this results embodying new methods might be circularise to practitioners in the form of a loose-leaf supplement t a standard textbook, the production of which would b one of the first jobs of the editorial and library com

---

[1] Miller, N. F. J. Amer. med. Ass. 1941, 117, 905.

We might then at last get a textbook which is readable and it could be kept constantly up to date by replacing obsolete information with new leaves. This textbook—or rather the series of them to cover all the special subjects—should be sent free to all members of the medical profession including students and the supplements would also be free. Though this would be an added burden on the public purse it would be in a good cause. An organisation for disseminating information on the latest methods of treating air-raid casualties already exists. The E.M.S. sends round circulars on official methods of treatment and is even collecting information on some subjects. An extension of this principle to the whole of medical practice could hardly be thought objectionable.

* * *

Let us then demand facilities for the proper organisation of research, for assuring the research worker a reasonable living, for leading him to the problems which most urgently require solution, for preventing him from engaging on redundant work, for providing him with an adequate resumé of all that is known about his chosen subject, and most important of all for getting the knowledge as quickly as possible to those whose job it is to use it. We need an organisation which, as H. G. Wells puts it, "accumulates, sorts, keeps in order and renders available everything that is known."

PALESTINE

MORTALITY AND SICKNESS AMONG INFANTS

THE infant mortality in the past ten years has been analysed in the July issue of *Hadassah*, the bulletin of the Jerusalem University Hospital. The deaths have been grouped according to the various races found in Palestine, and it is encouraging to find that the rate has fallen in all sections of the community. Thus over the period 1931–40 the rate has fallen from 186 per 1000 to 147 among Arabs, from 133 to 107 among Christians and from 81 to 59 among Jews. The infant death-rate is highest between April and September, the Palestinian summer months. Among Arab infants the summer rate is double that in winter, and among Jews half as much again as the winter rate. The commonest recorded causes of death are congenital debility, diarrhœa and enteritis and bronchopneumonia. Bograchow of the children's department at Tel Aviv, in an account of his experience with infantile diarrhœa during 1938–40, says that on the whole the disease affects older infants in Palestine than it does in Europe because almost all Jewish mothers breast-feed their infants, who are thus safeguarded against infection carried by cow's or goat's milk. *Nevertheless the social status of the family and the* nutrition of the infant are important in ætiology and prognosis. Thus infantile diarrhœa is very common among the poorer Jewish families. Nutritional disorders are also common and often associated with qualitative or quantitative hunger. He mentions a toxic form of infantile dysentery with a fatality of 100%.

POISONOUS BITES AND STINGS

J. Seide of Jerusalem, writing in *Harefuah*, reviews the poisonous fauna of Palestine. These include the jelly fish, *Rhizostoma pulmo* and *Aurelia aurita*, and the sea anemone, stings from which give rise to toxic skin eruptions. The bite of the centipede *Scolopendra cingulata* causes pain and swelling but is otherwise harmless. Spiders of the genus *latrodectus* are highly poisonous and a sting from one may endanger life in a child. *Tarantula albofasciata* is less poisonous. There are six different species of scorpion in Palestine, all of them poisonous. The commonest is the yellow *Buthus quinquestriatus*, which gives an extremely painful sting causing local inflammation and sometimes constitutional disturbance, though Seide had never seen a death from such a sting. Bees, wasps and hornets sting like their kin elsewhere and bites from ants are negligible. Several species of poisonous fish cause trouble to fishermen, including species of scorpæna and trachinus. The venomous snakes found are mostly vipers, the oriental form of the Levant viper being the most common in inhabited parts of the country; its bite may cause death, and prognosis depends chiefly on the promptness with which antitoxin can be given. Of 23 cases treated in hospital 3 were fatal. Bites from *Vipera lebetina* are discussed more fully by Lefkovitz in a separate paper. These are becoming commonest during the hotter months. The victim develops local and general signs among which circulatory disturbances are prominent; indeed vasomotor instability often persists for years after the bite. At the time of the injury œdema and hæmorrhages are common. Experiments on frogs suggest that the toxin attacks the vascular endothelium, causing progressive engorgement of the peripheral vessels; the condition spreads from the region of the bite. The patient develops hypotension, low temperature and myocardial failure with collapse and may die from circulatory failure. Treatment at present recommended is ligation of the affected limb and injection of serum.

PRECAUTIONS AGAINST MALARIA

Malaria is increasing in some of the northern districts. The health department of the Jewish agency and the university appointed a committee of inquiry under the *chairmanship of Professor Mar which reported some* months ago (*Hadassah*, March 1941). The committee advised that the tents and huts of the colonists should be provided with mosquito-nets and that specially constructed doors should be supplied to the huts. These recommendations are being carried out and the colonists are being instructed in keeping their irrigation canals clean and free from plants so as to discourage the breeding of the larvæ.

MILK FOR INVALIDS

UNDER the Ministry of Food's milk-supply scheme priority-supplies of liquid milk are allowed to certain invalids against a certificate given by a medical practitioner. The conditions qualifying for these special supplies are now specified in a list drawn up by the ministry's medical advisers and made public on Dec. 11, as follows:

Active tuberculosis of all types;
Silicosis;
Affection of the mouth, throat or gullet or organic nervous disorder causing interference with swallowing;
Gastric, duodenal or anastomotic ulcer;
Illness characterised by high and prolonged fever;
Post-operative conditions after major operations;
Active workers, including domestic workers, during an illness which temporarily incapacitates them for work;
Sick children not attending school;
Dyspepsia due to conditions other than ulceration of the stomach or duodenum;
Colitis; Diabetes mellitus;
Thyrotoxicosis; Nephritis;
Hyperemesis gravidarum, chorea of pregnancy, acute yellow atrophy occurring during pregnancy, albuminuria of pregnancy, eclampsia, which are of sufficient severity to entail total confinement to bed.

These diseases and illnesses are the only conditions for which special supplies of milk to invalids may be authorised by a medical practitioner. The quantity of milk allowed is at the discretion of the doctor, subject to a scale prescribed by the Ministry of Food.

FOUR observations in Dr. A. T. W. Powell's school report for WALTHAMSTOW call for comment—*decline in corneal* ulcer, decline in organic heart disease, decline in chronic otitis media, and increase in dental caries. These changes are common throughout the country. In 22,847 inspections and reinspections only one case of corneal ulcer was detected, yet formerly this disease was often found in school-children. It increased in incidence in the last war, but since then it has decreased almost to vanishing point, probably because of improved nutrition. The decline in chronic otitis is mostly due to greater attention to the treatment of the acute phase of the disease, but also in part to the lowered severity of scarlet fever and measles. The decline in heart disease and child rheumatism, which is noticed in all units with rheumatism clinics, is none the less welcome because its causes are obscure. The increase in dental caries, especially in infants, may be due to greater attention, but most dentists believe it to be genuine.

FUTURE OF MEDICAL RESEARCH

W W WALTHER M B LOND
DIRECTOR OF PATHOLOGY, QUEEN MARY'S HOSPITAL FOR THE EAST END

THERE is some justification for saying that we are living in the Golden Age of Medicine, for at no previous time have there been so many advances in such a short space For example, the sulphonamide group of drugs alone have revolutionised the treatment of many common conditions And yet there is still much room for improvement in the organisation which makes these discoveries possible Research does not consist simply of working out and publishing the results of an original idea Much time must be spent in reading through the literature of work already done on the subject, a task which may involve one in many strange languages, *only to find* perhaps at the end of many weeks of labour, that somebody else has already worked out the same problem but has somehow failed to get immediate recognition

In spite of the enormous volume of research which is published little of it ever finds its way into general use, partly because much of it remains unverified and partly because it is simply not noticed This does not sound at all like a golden age, but the statement is easily supported by facts For example, the original suggestion (based on sound observation) that the shock of burns should be treated by transfusion with a protein-containing fluid was made in the middle of last century Yet this very practical suggestion was overlooked and only rediscovered during the last few years Presumably nobody noticed it and it therefore failed to get verified On the other hand, some discoveries seem so much to catch the researcher's fancy that a vast and unnecessary amount of redundant work is wasted on one particular subject An example of this is the spate of literature which followed the first few *papers about prontosil and allied* drugs It has been estimated that the number of *papers* published on this subject is in the region of ten thousand Now even the most confirmed *sceptic would hardly* demand such a vast literature to convince him, and *many* of these papers are based on such a small number of cases that by themselves they would be of little significance And yet, until an enormous amount of work on any particular subject gets published, the general practitioner does not hear about it unless it concerns some material whose advertisements are pushed under his nose This is because the busy doctor has little time to wade through (or income to pay for) all of the large number of medical journals which are published today But there are *plenty of would-be* contributors to these journals, largely *owing to the fact* that besides the quest for knowledge and the desire to benefit humanity there is a need to attain personal recognition A few publications are a great *recommendation* for a job, with the result that, as Miller[1] *says,* "We find it necessary to digest an ever-increasing number of half-baked adventures in medical research" Often enough, in the haste occasioned by *the desire to be first in the field,* the work is scamped Sometimes this may also be due to lack of facilities to carry out some important detail of the work General practitioners have few facilities for accurate work or for *producing a number* of results sufficient to be statistically significant In this way a large potential army of keen men is immediately robbed of its keenness Or, if an effort is made, it lacks numerical weight Yet under skilled guidance individual efforts can often be turned to good account There is no dearth of subjects for research, but we lack an organisation which can apportion the work to the best advantage Although many people no doubt prefer to choose their own subject, it is probable that under a competent authority most would be prepared to work at some set problem either singly or as members of a team

Many believe that research is insufficiently endowed, and point out that the money available is usually only sufficient to support a newly qualified man, without domestic commitments, on a whole-time basis Now, there is no special virtue in whole-time research work, though one may be forced to devote one's whole time to order to do one's own reading Neither is it certain the newly qualified man, however keen is the best for research Admittedly, the ideas are *often su* by the head of a department while the actual w carried out by assistants, but this does not cover *should not cover the whole field of research*

The criticism of modern research thus falls three heads—inadequate endowment, lack of orga tion and a failure to get results embodied in practice reasonable space of time It is unlikely that the priv endowment of research will increase in the future, and best way out of the difficulty seems to be the deve ment of a part-time arrangement whereby anybody b paid by the state (and the number now is greater t ever before, and likely to be greater still) should allowed sufficient spare time to do research if the faciliti exist for it In certain circumstances a definite pri might be offered for the solving of some particul problem The prize of £10,000 offered by a daily news paper encouraged research into television, with the resul that, before the war, England led the world in this field and has since led it again in radiolocation

A CENTRAL BUREAU

For the proper organisation of research some respon sible controlling body would have to be set up This body would be equipped with an adequate library and a permanent staff whose duties would include the prepara tion of abstracts of all that is known on particular subjects in any language, so that the intending researcher is saved the trouble of reading a vast amount of lite[illegible] in order perhaps to clear up one small point In ad[illegible] they should be capable of giving up-to-the mi[illegible] information on any medical subject to any med[illegible] practitioner who asks for it, day or night This lo[illegible] a formidable task, but, with an efficient card-index an cross-referencing system, a trained staff would soon find no difficulty in giving rapid answers to questions The cost of maintaining such a library would be great, but it would be well worth it H G Wells, in his "Shape of Things to Come" had such a scheme for the card indexing of all knowledge—the "Memory of Mankind," with headquarters in Barcelona All research work, both current and projected, would have to be registered with the bureau, which would then be able to prevent anyone from engaging on redundant work It could also apportion the work to the best advantage, and organise the appropriate team for the rapid solution of special problems and for the verification of important observations in the shortest possible time Another important function would be the organisation of teams of general practitioners, with the use of laboratory facilities, to carry out research on minor ailments which do not usually find their way to hospital beds All this could only be done by an official body with wide powers which enjoyed *the confidence of the whole medical profession* Such a body should of course, be organised internationally, like the International Labour Office at Geneva, but as the post-war future is impossible to foresee a start should be made here The tendencies of foreign research should be watched and all allied and friendly neutral countries asked to participate in an exchange of medical knowledge

The results obtained would be examined for contradictions which could be dealt with immediately by repetition, they would then be submitted to statistical analysis and finally written up in collaboration with an editorial staff whose job it would be to compress the material into as small a space as would be consistent with clarity An accurate abstract would be prepared at the same time Important results might well be published in full in a separate international journal of research simultaneously produced in those countries which *participated, and the abstracts* would appear in the *regular journals*

The rapid dissemination of results important to practitioners would be the last and most important duty of the bureau As has already been pointed out, owing to the multiplicity of journals, results may never reach the people who would most benefit by them To correct this results embodying new methods might be circularised to practitioners in the form of a loose-leaf supplement to a standard textbook, the production of which would be one of the first jobs of the editorial and library comittee We might then at last get a textbook which as readable and it could be kept constantly up to date y replacing obsolete information with new leaves This extbook—or rather the series of them to cover all the pecial subjects—should be sent free to all members of he medical profession including students and the upplements would also be free Though this would be n added burden on the public purse it would be in a ood cause An organisation for disseminating informaion on the latest methods of treating air-raid casualties lready exists The E M S sends round circulars on fficial methods of treatment and is even collecting nformation on some subjects An extension of this rinciple to the whole of medical practice could hardly e thought objectionable

---

* * *

Let us then demand facilities for the proper organisation of research for assuring the research worker a reasonable living for leading him to the problems which most urgently require solution, for preventing him from engaging on redundant work, for providing him with an adequate résume of all that is known about his chosen subject, and, most important of all, for getting the knowledge as quickly as possible to those whose job it is to use it We need an organisation which as H G Wells puts it ' accumulates sorts keeps in order and renders available everything that is known "

PALESTINE

MORTALITY AND SICKNESS AMONG INFANTS

THE infant mortality in the past ten years has been analysed in the July issue of *Hadassah*, the bulletin of the Jerusalem University Hospital The deaths have been grouped according to the various races found in Palestine, and it is encouraging to find that the rate has fallen in all sections of the community Thus over the period 1931–40 the rate has fallen from 186 per 1000 to 147 among Arabs from 133 to 107 among Christians, and from 81 to 59 among Jews The infant death-rate is highest between April and September, the Palestinian summer months Among Arab infants the summer rate is double that in winter and among Jews half as much again as the winter rate The commonest recorded causes of death are congenital debility, diarrhœa and enteritis, and bronchopneumonia Bograchow, of the children's department at Tel Aviv in an account of his experience with infantile diarrhœa during 1938–40, says that on the whole the disease affects older infants in Palestine than it does in Europe because almost all Jewish mothers breast-feed their infants, who are thus safeguarded against infection carried by cow's or goat's milk Nevertheless the social status of the family and the nutrition of the infant are important in ætiology and prognosis Thus infantile diarrhœa is very common among the poorer Jewish families Nutritional disorders are also common, and often associated with qualitative or quantitative hunger He mentions a toxic form of infantile dysentery with a fatality of 100%

POISONOUS BITES AND STINGS

J Seide of Jerusalem, writing in *Harefuah*, reviews the poisonous fauna of Palestine These include the jelly fish, *Rhizostoma pulmo* and *Aurelio aurita* and the sea anemone, stings from which give rise to toxic skin eruptions The bite of the centipede *Scolopendra cingulata* causes pain and swelling but is otherwise harmless Spiders of the genus *latrodectus* are highly poisonous and a sting from one may endanger life in a child *Tarantula albofasciata* is less poisonous There are six different species of scorpion in Palestine, all of them poisonous The commonest is the yellow *Buthus quinquestriatus*, which gives an extremely painful sting causing local inflammation and sometimes constitutional disturbance, though Seide had never seen a death from such a sting Bees, wasps and hornets sting like their kin elsewhere, and bites from ants are negligible Several species of poisonous fish cause trouble to fishermen, including species of scorpæna and trachinus The venomous snakes found are mostly vipers, the oriental form of the Levant viper being the most common in inhabited parts of the country, its bite may cause death, and prognosis depends chiefly on the promptness with which antitoxin can be given Of 23 cases treated in hospital 3 were fatal Bites from *Vipera lebetina* are discussed more fully by Lefkovitz in a separate paper These are becoming commonest during the hotter months The victim develops local and general signs, among which circulatory disturbances are prominent, indeed vasomotor instability often persists for years after the bite At the time of the injury œdema and hæmorrhages are common Experiments on frogs suggest that the toxin attacks the vascular endothelium, causing progressive engorgement of the peripheral vessels, the condition spreads from the region of the bite The patient develops hypotension, low temperature and myocardial failure with collapse, and may die from circulatory failure Treatment at present recommended is ligation of the affected limb and injection of serum

PRECAUTIONS AGAINST MALARIA

Malaria is increasing in some of the northern districts The health department of the Jewish agency and the university appointed a committee of inquiry under the chairmanship of Professor Mar, which reported some months ago (*Hadassah*, March 1941) The committee advised that the tents and huts of the colonists should be provided with mosquito-nets, and that specially constructed doors should be supplied to the huts These recommendations are being carried out and the colonists are being instructed in keeping their irrigation canals clean and free from plants so as to discourage the breeding of the larvæ

MILK FOR INVALIDS

UNDER the Ministry of Food's milk-supply scheme priority-supplies of liquid milk are allowed to certain invalids against a certificate given by a medical practitioner The conditions qualifying for these special supplies are now specified in a list, drawn up by the ministry's medical advisers and made public on Dec 11, as follows

Active tuberculosis of all types,
Silicosis,
Affection of the mouth, throat or gullet or organic nervous disorder causing interference with swallowing,
Gastric, duodenal or anastomotic ulcer,
Illness characterised by high and prolonged fever,
Post operative conditions after major operations,
Active workers, including domestic workers, during an illness which temporarily incapacitates them for work,
Sick children not attending school,
Dyspepsia due to conditions other than ulceration of the stomach or duodenum,
Colitis, Diabetes mellitus,
Thyrotoxicosis, Nephritis,
Hyperemesis gravidarum, chorea of pregnancy, acute yellow atrophy occurring during pregnancy, albuminuria of pregnancy, eclampsia, which are of sufficient severity to entail total confinement to bed

These diseases and illnesses are the only conditions for which special supplies of milk to invalids may be authorised by a medical practitioner The quantity of milk allowed is at the discretion of the doctor, subject to a scale prescribed by the Ministry of Food

---

FOUR observations in Dr A T W Powell's school report for WALTHAMSTOW call for comment decline in corneal ulcer, decline in organic heart disease, decline in chronic otitis media and increase in dental caries These changes are common throughout the country In 22,847 inspections and reinspections only one case of corneal ulcer was detected, yet formerly this disease was often found in school-children It increased in incidence in the last war, but since then it has decreased almost to vanishing point, probably because of improved nutrition The decline in chronic otitis is mostly due to greater attention to the treatment of the acute phase of the disease but also in part to the lowered severity of scarlet fever and measles The decline in heart disease and child rheumatism, which is noticed in all units with rheumatism clinics, is none the less welcome because its causes are obscure The increase in dental caries, especially in infants may be due to greater attention, but most dentists believe it to be genuine

’t know officially what they make in that building they always start up that motor with its funny little phut-phut exhaust just as I come round this Yes Jerry did have a crack at it one day, he hit the sea and bent those rocks a bit They lly hit the sea round these parts ")

Now for the final straight the skipper has sighted us is starting up the engine as a hint that we should ke some show of running because of course I am just minute late—it always ends that way At first the pper didn t take to me at all kindly said he was shed if he'd wait for me or any other dashed doctor somehow he always does wait (' Look at those k flowers I don't know what they re called but you'll d an amazing variety of flowers leading a fairly comfortable existence among the crevices of the rocks, even n to the water's edge I can't imagine how they do because this breakwater is fiendish in all winter ather often in spring sometimes in summer and it be deadly in autumn Only a week ago it was so gh that not a single boat could put off—the wind stles through the telegraph wires flings the sea across e breakwater roars into one's eardrums freezing them agonising deafness and threatens all the time to dash on to the rocks below ")

"Good morning skipper ' "Mornin Sir, let 'er go k.' We take shelter in the wheel house "What's I hear about a new doctor Sir? terrible it is why we just get to know one when they sends us another there perhaps he'll get up betimes in the morning I shan t be so behindhand with my work all day ' s a pity that the skipper will no longer be able to start working day with this masterly exaggeration

To any Englishman this twenty-minute journey across enormous harbour would be fascinating to a man d to reaching his daily work by bus tram or tube it is holiday Today it is true, the harbour is almost empty, one day the traveller will see H M S well he see various units of the Royal Navy he will see rchantmen of all shapes and sizes and nationalities wlers and drifters seaplanes prizes that once flew swastika or were built in Genoa or Naples and he will ce many other things that are best left unwritten "No I've never disgraced myself on this boat, though there are occasions when it is hard work for two men to swing the wheel and hold it, especially outside the boom in one of these sou'westers that blow up so suddenly hereabouts And I could tell you a story about the sergeant-major of the Battery that we are about to visit, but perhaps it would be fairer to let you wait for that one until, in a sudden confidence, he tells you the sorry tale himself.") The fort, from being a rounded blob in the early-morning haze now begins to take shape and to stand out black and defiant against the horizon Seagulls wheel and circle, alight and take wing in a continuous poem of movement, their skirling pierces the sea-born silence ' Well here we are, good-bye, skipper, I shan't be seeing you again because we'll return in the *Ladybird* " "Mornin' Sir best of luck to you "

The party waiting to go ashore for day leave always present something of a problem It is not easy to make a correct and dignified return to their grinning salutes when one is concentrating on a perilous scramble up a slippery ladder And now for our second breakfast "Hello, doc, are you back again already? Oh well it's your last day, thank heavens, so I suppose we must be grateful for small mercies! " I wonder how long it will be before they have such a cheerful greeting for my successor now being treated with meticulous politeness A matter of a few days only, I expect, the traditional reserve of the Englishman is soon dissolved in these friendly surroundings As we leave the main door of the fort after our cups of tea I automatically clutch at my cap There is always a breeze lurking round the corner waiting to toss one's headgear to the waiting waves After it had twice caught me out, and I had proved that the cap S D, does not stand up to immersion in sea-water I resolved it would never happen again or if it did that at least it would not cost me so dear I have learned to appreciate the troops' "fore-and-aft "

* * *

Great work has been done by the Ministry of Health in the provision of amenities at rest centres where homeless people may be drafted after a severe raiding incident Arrangements are made for the primary comforts of shelter, a cup of hot tea, blankets to encourage sleep food for the hungry and medical and nursing care for the sick Loyal workers of all kinds have been earmarked—W V S school nurses health visitors, district nurses, Civil Nursing Reserve public-assistance officers public-health medical officers and so on The storage cupboards at the centres are a feast for rationed eyes, with their shelves of tinned and bottled goodies that have long since departed from the shop window One thinks of the dark cloud and its silver lining and turns sadly away with the sublinguals working at top pressure Going round some of the centres recently it struck me how much was being attended to in the material sense how little in the spiritual If I thought we are compounded of body and soul where does the soul side come in during the drab hours? Of course there are the encouraging word the cheery smile, the friendly pat on the shoulder But these things are individual and do not necessarily affect the mass and the morale of the mass is on all counts very important In addition to all the voluntary helpers the ministry should see that a gleeful soul with a piano-accordion is on the centre staff—one who can play "Roll Out the Barrel" and sing "Begone, Dull Care" As musician he might be more than any other, entitled to wear the mystic letters 'A R P'.

Parliament

QUESTION TIME

Students and National Service

Mr E BEVIN, minister of labour and national service informed Sir ERNEST GRAHAM LITTLE that the lowering of the age of call-up to include men born in 1923 would not affect the arrangements made for students following specified scientific or technical courses Other male students at the universities who were in the 1923 age-class might apply to the university joint recruiting boards and if they received a favourable recommendation they might after enlistment into one of the fighting services be placed to the reserve and subject to the exigencies of the service complete one year at the university while receiving training in the senior training corps or the air training squadron These arrangements would not extend to students who had already completed three terms at the university At present it was not intended to call up women under the age of 20 The arrangements for women students over 20 were being considered

Central Medical War Committee

In answer to a question Mr E BROWN the minister of health, stated that the services committee which the Central Medical War Committee has authorised to deal with questions affecting the recruitment of individual medical practitioners to H.M Forces and other cognate matters, has met 17 times in the 12 months ended Nov 30 last The attendances were as follows

Industrial Health Research Board

Replying to Mr F MESSER Sir JOHN ANDERSON the lord president of the council, said The Secretary of the Industrial Health Research Board is Sir David Munro who is sixty three years of age He is at present giving part of his time to the Ministry of Supply as chief medical adviser but in view of that a senior member of the board's investigating staff

In England Now

A Running Commentary by Peripatetic Correspondents

THE little I know about Japanese mental processes, so different from ours, inclines me to believe that their communiques will be even less reliable as a source of news, but more indicative as to intentions, than the German ones The Hun mind starts off with the raw material truth halves it doubles it, twists it or suppresses it according to need but at any rate starts with it as a basis, a relic of a code of morals that bound and helped to evolve the European world The Jap uses truth like steam to be harnessed to man's use if required to be replaced by pure invention, like some of those landings, if a trap demands My mind goes back to a time when I nosed about on the outskirts of their ports, Nagasaki, Yokohama Kobe , got the same feeling as I do with dogs and birds at home—that here are minds working in different ways to mine—and played at putting myself in their place I remember the points where I *seemed to come in contact with them the "soil sense"* and my sympathy with the jinrikisha man who hoarded his daily urine in a tin to bring back to his little terraced garden , their sense of beauty, the single flower with a background, which seemed to me to be a reflection of the stamped beauty of the inland sea , the infinite patience and delight of the growers of dwarfed trees , the public hot baths and their sensual skin pleasure of cleanliness , the small boat men, their love of the sea and the tides, and their fear of it Those seemed to be the tiny points of contact , far away I sensed a religious nationalism which was as foreign to me as our moral system with its emphasis on sex is to them There is a certain satanic humour in the *facts that in this war with Japan—a real war between* sub-species—she should be allied to those who make a fairy story of race purity and world domination and fighting against those whose industrialism has been at the same time the source of her strength and her poison

* * *

As a relief from the world war Mr A P Herbert's word warriors will find a happy hunting ground in the recent B M A report on Industrial Health in Factories A few points can even be scored off the title itself because health, unlike peace, is apparently divisible, the implication being that in addition to "industrial" health other types of health are to be found in factories The word "industrial" keeps cropping up like King Charles's head Thus "an industrial medical officer is appointed to a factory" , it is not possible to appoint a doctor to a factory, he must be an "industrial medical officer" even before he has had any experience of factory life Again, a new specialty called "traumatology" is to be fostered and attention is called to the scarcity of trained "traumatologists" in the country It appears that the ordinary doctor has had no training in treating injuries In due course we shall undoubtedly get subdivisions of the new specialty, such as cephalotraumatologists, thoracotraumatologists and even digitotraumatologists One can already visualise the necessity for a new society to be called the Association of Philotraumatologists Then there is a crying need for doctors constantly to attend postgraduate lectures (for after all there is nothing like a continual state of postgraduateness for keeping doctors out of mischief) so that they may understand more fully the fact—as yet imperfectly recognised—that when somebody is whacked with a rubber truncheon a solution of continuity might arise anywhere in that body's body, depending on the part whacked and the nature of the earth's crust on to which the whackee might fall *No-one but a skilled traumatologist of some* years' experience in Birmingham would be entitled to repair the breach A mobile air-borne team of traumatologists should be kept champing on the air-screw so that they might dash off to Land's End or John o' Groats at the slightest provocation, and particular care must obviously be taken to include in the team relays of digitotraumatologists because cut fingers are so common, don't you know ! Wounds will no longer be sewn up with surgical needles and catgut or silk, but with traumatological aiguilles and tautological byssofils

* * *

I'm imprisoned *hopelessly deep* down in a dungeon , how did the old saw go? "Down in a deep dark ditch lay an old cow " No, that doesn't seem to fit, anyway it's deep and it's dark, and there seems to escape , my tongue is swollen, I can't even whisper, alone shout for help How can I get at that man keeps yelling in my ear, "Come on Sir come on Suddenly the shouting swells to a terrific volume of very close to my ear I seem to be climbing through roof but the prison suddenly resolves into the r that my blankets have got twisted round me I m tl and the camp bed is too small for an expansive so nightmare "Oh, all right George, I can hear you n yes, I'll get up , yes, thank you George, I know the t cold , I never hear when you call me first w that, only five more minutes ? O K , George, I m up you needn't worry any more "

My batman and I have, between us, accomplished most difficult job in the day—getting me out of I always intend to have half an hour at least for was and dressing, but as often as not it ends by being certina-ed into five minutes With the mists of sleep clinging to my eyes I stumble into breakfast , usuall *solitary meal (the M O always has to get up before* body else), but this morning I find another man, the M O replete with breakfast, impatient to be off "W Durrant I see you've taken to heart the tip I gave last night about getting up early enough to eat a d breakfast " "Don't worry, there's still some food l I switch on the wireless, *explaining that as soon as* announcer has mentioned how many raiders were England during the night it is time for me to get g I can tell from the look on Durrant's face that I am ing my breath, and that he will always be on his wa before the announcer gets near the microphone persist manfully in giving him *all the petty details o daily task, helping him metaphorically over many s* that seemed difficult to me at first because as I tell I was the first doctor appointed to do regular round this chain of forts

Crossing the parade ground we glance back at windows now beginning to fill as the shavers *thrust t* white-lathered faces out for that first breath of morn air, and I tell Durrant about a photograph that I l forward to procuring from the Nazis when we ve bea them Three mornings in succession, at the same ti they came over and snapped me just as I was crossing parade ground I should like to know what I look l from 30,000 feet Barely controlling his self-righte ness at noting that the sun is not yet above the houset Durrant is a little abashed when I point out that ne all the essential services of life have already finished t morning round the postman has been, the baker' gone, we had fresh milk with our breakfast the ne papers only just miss us "And anyway," I remind l "this is nothing to the winter , why it's pitch-dark t when you set out to catch the boat "

Every morning (although I never have time to to do it) I almost catch my breath as I burst through mouth of a little alley on to a pathway in full sight of sea The path trots down some steps and joins a roa curve round a tiny bay leading us along to a small where the boat waits each morning It takes minutes to walk round that little bay, never dull or there has always been the excitement of trying to to the boat in time, as well as the exciting beauty of t inlet, with the harbour on the far side of the breakwa an ever-changing pool of ships and far away the o sea There have been still, frozen winter mornings w the "bowl of night" has lingered mirrored in the wate mornings when the sun has only winked a solemn above the horizon's edge disliked the *prospect* sought slumber *again* under black blankets of clo mornings when the sun has pointed a fiery finger acr the flat grey sea, touching one with warmth and beck ing the soul to infinite distance ("Be careful down th steps, they're very slippery in winter ") Morni when there was rain, biting in winter, flooding in spr splashing in summer, or just a film of damp uncomf able mist ("Buy an oilskin', it doesn't look v military, and it won't get you a salute from an A B it's worth more than you pay for it No I'm afr mine isn't for sale ") Days when the clouds are s creamy pillars of down, jagged snow-capped peaks grey mountains, or growling muttering, crackling bla ness shooting tongues of livid fire *across the sky* ("

don't know officially what they make in that building, as they always start up that motor with its funny little phut-phut exhaust just as I come round this corner Yes Jerry did have a crack at it one day, but he hit the sea and bent those rocks a bit They really hit the sea round these parts ")

Now for the final straight the skipper has sighted us and is starting up the engine as a hint that we should make some show of running because of course I am just a minute late—it always ends that way At first the skipper didn't take to me at all kindly said he was [illegible] if he'd wait for me or any other dashed doctor but somehow he always does wait (Look at those pink flowers, I don't know what they're called but you'll find an amazing variety of flowers leading a fairly comfortable existence among the crevices of the rocks even down to the water's edge I can't imagine how they do it because this breakwater is fiendish in all winter weather often in spring sometimes in summer and it can be deadly in autumn Only a week ago it was so rough that not a single boat could put off—the wind whistles through the telegraph wires flings the sea across the breakwater, roars into one's eardrums, freezing them to agonising deafness and threatens all the time to dash one on to the rocks below ")

"Good morning, skipper " " Mornin' Sir, let er go back.' We take shelter in the wheel house " What's this I hear about a new doctor Sir? terrible it is why we only just get to know one when they sends us another But there perhaps he'll get up betimes in the morning and I shan't be so behindhand with my work all day' It is a pity that the skipper will no longer be able to start the working day with this masterly exaggeration

To any Englishman this twenty-minute journey across the enormous harbour would be fascinating to a man used to reaching his daily work by bus, tram or tube it is a holiday Today it is true the harbour is almost empty, but one day the traveller will see H M S , well he will see various units of the Royal Navy he will see merchantmen of all shapes and sizes and nationalities trawlers and drifters, seaplanes prizes that once flew the swastika or were built in Genoa or Naples and he will notice many other things that are best left unwritten

" No I've never disgraced myself on this boat, though there are occasions when it is hard work for two men to swing the wheel and hold it, especially outside the boom in one of these sou'westers that blow up so suddenly hereabouts And I could tell you a story about the sergeant-major of the Battery that we are about to visit but perhaps it would be fairer to let you wait for that one until, in a sudden confidence, he tells you the sorry tale himself ") The fort, from being a rounded blob in the early-morning haze now begins to take shape and to stand out black and defiant against the horizon Sea-gulls wheel and circle, alight and take wing in a continuous poem of movement their skirling pierces the sea-born silence ' Well here we are · good-bye skipper, I shan't be seeing you again because we'll return in the *Ladybird* " " Mornin Sir best of luck to you '

The party waiting to go ashore for day leave always present something of a problem It is not easy to make a correct and dignified return to their grinning salutes when one is concentrating on a perilous scramble up a slippery ladder And now for our second breakfast Hello doc, are you back again already? Industrial Health Research Board

Replying to Mr F MESSER, Sir JOHN ANDERSON the lord president of the council said The Secretary of the Industrial Health Research Board is Sir David Munro who is sixty three years of age He is at present giving part of his time to the Ministry of Supply as chief medical adviser but in view of that a senior member of the board s investigating staff is acting as joint secretary. There are thirteen full time investigators (none medically qualified) whose names and qualifications are as follows T Bedford, D SC, E G Chambers, M A, F A Chienko, W M Dawson, B SC, E Farmer, M A, Miss Alice Heim, PH D, D E R Hughes, B SC, R Marriott, B SC, Miss May Smith, D SC, F G L Stock, C G Warner, PH D, H C Weston, M I I E, and S Wyatt, D SC

Mr MESSER Does the Minister not think that this important post ought to be a full time job, especially as it was so during the last war?—Sir J ANDERSON Normally it is a full time job, but Sir David Munro is giving much needed help in the ministry of supply, and so far as his time is not available to the board, the gap is filled by the temporary appointment of a senior member of the staff.—Mr MESSER Is the Minister aware of the grave dismay with which the public have received the report of the British Medical Association that not less than 32,000,000 weeks are lost each year by industrial workers through preventable illness?—Sir J ANDERSON The business of the board is not primarily concerned with industrial disease, but with such matters as industrial fatigue, and the like

Medical Practitioners as Combatants

Sir ERNEST GRAHAM LITTLE asked the Minister of Labour how many registered medical practitioners were at present serving as combatants in any of the fighting services; and whether, in view of the shortage of medical personnel for both civilian and military needs, he would allocate such practitioners to medical duties.—Mr BROWN replied Arrangements have been made to secure that normally a registered medical practitioner may serve in H M Forces in a medical capacity only and although I cannot give a precise figure I have reason to believe that the number serving as combatants is negligible. The matter referred to in the last part of the question appears to be for the Service ministers who agree that it is only in exceptional circumstances that a medical practitioner may be employed in a non-medical capacity

Soldiers in Medical Category C

Captain H D R MARGESSON, secretary of state for war, replying to Mr F J BELLENGER said that many soldiers of medical category C were at present performing useful service in the Army by freeing men of higher categories for more active duties, and in view of the present man power situation he could not agree to their automatic discharge. Where application was made for the release of an individual for work of national importance the soldier's medical category was taken into account

Hospital Staffs

Major G OWEN asked the Minister of Labour whether, in view of the shortage of nurses and domestic staffs in hospital, he is prepared to recognise such service as a form of national service.—Mr G TOMLINSON replied I recognise service on the nursing and domestic staffs of hospitals as one of the most important forms of national service. It is included in the short list of vital war work for women for which women registered under the Registration for Employment Order are required.—Major OWEN Is Mr Tomlinson aware that many hospitals are short of domestic staff? Is it not a corollary of this order that the Minister will now be able to direct women with experience of domestic service to these hospitals, as he is able to do into the Armed Forces?—Mr TOMLINSON, I should require notice of that question.—Sir JOSEPH LAMB Is Mr Tomlinson aware that the women who are being sent now are daily workers, who arrive at 8 o'clock and leave at 5, consequently there is no one to take charge of the early or late work?—Mr TOMLINSON Hospitals, like all other institutions and industrial organisations, are having to do the best they can with the material available.—Sir J LAMB With the best will in the world, how can they wait till 8 o'clock to give all the patients their breakfast?—Major OWEN Is Mr Tomlinson aware that there are institutions of this character which have no cook at all? The matron of one hospital, to my own knowledge, on Sunday last had not only to look after the dressing of the patients, but to cook dinners for 14 people.—Mr MESSER Before the department considers compelling anyone to work at a hospital, will Mr Tomlinson do his best to see that the remuneration of the lower paid staff is improved?—Mr TOMLINSON I will consider all the suggestions that have been made

Detained Persons and Insurance Benefits

Miss F HORSBRUGH informed Mr DAVID ADAMS that regulations would shortly be made under powers conferred by section 8 of the National Health Insurance Act 1941 by which persons detained under Regulation 18B who before detention were entitled to N H I benefits would be opportunity to safeguard their health insurance and tory pension rights by paying within a reasonable per their release contributions at a reduced rate for the their detention. The reduced rate of contribution in these circumstances made due allowance for the such persons were not in a position to obtain health benefits during their detention. Replying to a f tion, Miss HORSBRUGH said that there would be a time after these people were released before they arrear in respect of contributions

Letters to the Editor

PSYCHIATRISTS AND THE RECRUIT

SIR,—I have been much impressed recently number of patients one sees who are invalided the Forces on account of mental illness. This is ol uneconomic and wasteful in two respects. These and women have to be equipped and trained and sumably cost the country a considerable amount money for short and unsatisfactory terms of service, well as taking up hospital time and accommo before discharge. In addition many of them are who, while they have a precarious adjustment to have done and could do useful work in civilian their mental equilibrium were not disturbed by the to adjust to unfamiliar and distasteful co say nothing of combatant service. We are told these conditions are caused by an insufficient psychiatrists to advise recruiting boards, and to early and slight anxiety cases in the Forces. M the time available for treatment must necessarily taken up in diagnosis and disposal of so much un material. Is it not time that the available psychiatric *personnel of the country were more thoroughly mobilised?* There are still many qualified and experienced women psychiatrists upon whose services no national call has been made, and the institutions for the chronic mentally sick boast many highly qualified and experienced psychiatrists whose work hardly, in this national emergency makes the demand upon them which they would probably welcome

Harley Street, W 1 MARION GREAVES

FRACTURED FEMORAL NECK

SIR,—The outlook expressed by Mr Cochrane on plaster treatment of fractures of the neck of the fe must seem to some surgeons retrogressive. Surely the greatest gain that pin fixation of these fractures has brought is the diminution of the mortality-rate due to hypostatic pneumonia. A patient whose fractured femoral neck has been pinned can straightway sit up and do breathing exercises, and in a few weeks he can be up and out on crutches—instead of spending three months in bed between sandbags or splints, or having his chest and abdominal muscles badly hampered by a Whitman type of plaster spica

Mr Cochrane's note that in spite of considerable experience of these fractures he has not had a case of aseptic avascular necrosis needs some further explanation. He states that many of his cases became arthritic, and one would have thought that if the X rays of some of his arthritic cases had been examined at the critical period of 6–8 weeks after the fracture they would have shown death of the head. Failure to spot avascular necrosis at this stage, as pointed out by Watson Jones here and by Phemister in Chicago, usually results in an arthritis. They considered that unless the head of the femur is protected, during this stage of revascularisation, from the traumata of movement or the compression of weight-bearing, distortion and exfoliation of cartilage leading to arthritis must result. As Watson Jones points out in his book, fixation by pinning secures apposition with firm fixation of the fracture line and this, coupled with an absence of weight-bearing, is essential if the head is to be revascularised. May not the torsional strain, which must fall on the fracture callus when Mr Cochrane allows early movement of the knee out of his plaster spicas, be responsible for some unrecognised cases of avascular necrosis? And these cases, though union by bone is possible, usually end up as arthritics unless they are carefully treated

National Temperance Hospital N W 1 G O TIPPETT

HOSPITAL DESIGN

,—The modern hospital is a complex instrument it must be designed by those who are to work within lls The R S M discussion (*Lancet* Dec 13, p 737) timely It is impossible for an architect to design pital alone, he must have the cooperation of the cal staff This entails a great deal of thought on the of the medical men concerned and coöperation and nce on the part of the architect In one hospital, whose design I in conjunction with my medical agues was to some small degree responsible, sixteen were prepared before the final one was chosen r hospitals where this cooperation was lacking and h have left design to architects are saddled with tisfactory buildings Many instances of this could ven, but I will cite two In a medical school which recently been rebuilt, the lecture theatre cannot be d in winter The heating is by warm air blown into room and when it is turned on is so noisy that the er cannot be heard The seats are built at such an that in order to be heard by the audience at the he has to have his head permanently hyper-nded Similarly in a newly erected private block is no sound insulation between the patients' rooms tween the floors

would therefore urge strongly that the staff of any ital that contemplates rebuilding should get together ar or so beforehand and make up their minds what want, and where they want it down to the minutest ils, and not to place reliance upon an architect who estly is unable to design such a technical instru-t as the hospital has become

arley Street, W 1 DAVID LEVI

NEW METHOD OF TREATING STAMMER

R,—The view that stammering is a symptom whose must be sought in the psychological field has been hed independently by medical psychologists and ch therapists Study of its character and develop-t shows that different types of stammering represent rent stages of the same disorder In the develop-t of a stammer, the sequence of stages is the opposite hat found in normal development and evolution of ch; we are therefore justified in thinking of stam-g in terms of Hughlings Jackson's theory of dissolu-in the nervous system—the reversion (or regression) lisease to progressively more primitive types of tion The first stage of stammering is now generally rded as due to a dissociation between thought and rance This disharmony leads to the reiteration of bles, words or phrases (clonic stammer), a primitive of utterance comparable to the prelinguistic bling in the child's speech development The forces ch bring about a dissociation between thought and ch are usually but not necessarily emotional, at the t they are unconscious to the mind of the speaker, may remain so for some time Unfortunately titive speech is stigmatised by those around the merer as "bad." "slovenly" or "childish", he ures the same misconception, endeavours to improve speech and is exhorted to do so But since the nature is disorder is unrecognised, the steps he takes in order top the reiterations are erroneous and lead him into second stage of stammering, characterised chiefly by ertense articulation (tonic stammer) This hyper-city represents those primordial hypertense postures ch symbolise aggressive emotions Once more the merer can see no way out This blind-alley situa-recurs at intervals, entailing a number of character- stages, and ultimately leads to complete discourage-t and resignation

edical psychologists deal with a stammer in accord- with their views on the nature of the neuroses, ch therapists chiefly use relaxation suggestion, uasion diversion or even philosophical methods (for mple the stoic doctrine) All these methods over- the fact that stammering develops in stages If a n stammerer's symptoms symbolise landmarks in efforts to grope his way along the blind alley, treat-t should permit and encourage him to go back in his ner of speech to the point where he diverged from the t track This point is marked by reiterative (clonic) rance Unfortunately, to the stammerer and those ontact with him to speak in this babbling way means to stammer worse Actually such speech is nearer to normal speech than any mode of speaking which he may have acquired on his way through the blind alley The lack of hypertonicity in such reiterated utterances suggests to the patient the truth of this fact and he readily admits it, nevertheless the therapist's endeavours to induce him to retrace his steps to the clonic stage may meet with considerable resistance, the patient feels that the ostensibly babyish reiterated speech must increase his social difficulties However in suggesting the reversion, the therapist sanctions that infantile speech which has long been repressed, and thus acts as a symbol of the parent figures of the patient's infancy—a procedure sometimes leading to difficulties which cannot be dealt with here

The method outlined has given promising results in a series of cases, and I draw attention to it at this stage because it may prove useful in treating cases precipitated by war stress

Tavistock Clinic LEOPOLD STEIN.

VOLPAR PRODUCTS

SIR,—In a recent paper (*Human Fertility* February 1941, p 1) Dr R L Brown and Dr C J Gamble describe their technique for testing the in-vitro efficiency of commercial spermicidal products Their findings place Volpar at the head of a list of a number of such products, thus confirming the findings of Dr J R Baker This preparation was devised as a result of nearly ten years research by Dr Baker and Dr H M Carleton (whose joint book was reviewed in the *Lancet* 1936, 1, 1071) and was only then put on the market Dr Brown and Dr Gamble raise two important points that contraceptive efficiency measured by laboratory methods does not necessarily tally with clinical experience, and that volpar contains a mercurial compound which has not yet been shown to be harmless when used regularly over a long period The first point can only be settled by reports on clinical results, preferably recorded in a uniform and comparable way The Family Planning Association had hoped to publish such evidence but the war has interfered with the collection of records, information is, however, slowly accumulating and will be published in due course And with regard to the second point, no evidence of cumulative toxic action has been anywhere recorded I have myself had under observation for periods ranging from 1 month to 4½ years more than 500 patients regularly using volpar products, and in no case has there been any sign of mercurial poisoning

MARGARET HADLEY JACKSON

CORONER'S COMMENT —The quotation in Dr Carling s letter (*Lancet*, Dec 13 p 748) should read " your duty to comment on the *number* of the staff at the hospital "

Obituary

"WELSH OF FELTON"

, Dr Robert Anthony Welsh succeeded to the practice of Dr Edward Anthony Hedley of Felton, Northumberland married Hedley's daughter, and lived for 47 years in a Jacobean house known as "Peth Foot" which had been the home of a line of country doctors, father to son, for four generations His life was as he said himself, largely occupied in going to and fro, on some days he might travel 40 miles, seeing only four or five patients, and after he gave up his horses for a steam car and then a petrol car of French make he might still have to improvise a stretcher to carry an emergency case a mile or more over heathery moor Difficult midwifery must be done single-handed and fractures were treated at home Next to the motor-car the installation of the telephone brought the greatest change into his life It is an old and inspiring story which he was induced while still in practice to tell in these columns under the heading ' The Doctor's Day "—in the depths of the country It was the life of his choice and if he had had his time over again he would still have been a country doctor Welsh was born in 1864 and qualified at Newcastle in 1891, when he retired three years ago it was only to move nearer to Newcastle, where he died on Nov 21 And his son, Dr Edward Anthony Welsh, carries on the practice

MEDICINE AND THE LAW

A Soldier dies of "Not Culpable Negligence"

UNDERSTAFFED as they may be, and preoccupied with the task of administering medical services without *properly trained personnel, the military authorities* will doubtless pay attention to the remarks of the coroner who recently investigated the death of a soldier at Llangollen Our readers can form their own conclusions from the story and can decide the steps they would take *to prevent the possibility of a similar occurrence*

Gunner Bird, R A, aged 23, was the cook at a regimental medical post Having a cold, he asked the V A D nurse at the post for some medicine She gave him a cough mixture At about 10 P M on the next night (a Saturday) he went to the dispensary again for something for his cold, he asked for something different from the medicine of the previous night, because the cough mixture had done him no good She gave him a dose of phenol, a teaspoonful in half a cup of water He said it tasted strong, she gave him a cup of hot water He said he was going to be sick He went to the sink, he was not sick but said he had "needles and pins all over" The nurse shouted for another nurse stationed at the post and the corporal in charge (who is responsible in the absence of the medical officer) was fetched The corporal telephoned for the doctor and gave Bird a solution of salt and water Having learnt what had happened, and given hurried instructions, the doctor went to his surgery to collect his bag and stomach-tube While he was there, a second telephone message came, Bird's condition was worse and the nurses could get nothing down his throat The doctor dashed to *the post by car and found Bird in a* comatose state, his symptoms were consistent with carbolic-acid poisoning The stomach-tube was tried and the doctor did what he could, but the patient soon afterwards died The medical officer in charge of the post, a major of the R A M C, had remained there till *4 o'clock on this Saturday afternoon*, he had telephoned at 9 30 P M and been told that everything was in order, he was summoned by telephone at 10 40 and went immediately to the dispensary where he found Bird dead

The inquest elicited the following evidence The nurse gave Bird the phenol because she "thought it was the same thing as she had bought from a chemist at Preston and had taken herself" She was a V A D with two years' experience in an emergency hospital, this included night duty for nine months during which she gave out medicines in accordance with doctors' prescriptions She did not know the strength of the phenol, had not seen it *given for a cold* or as a gargle, and was unaware that it was used for sterilising instruments No-one had warned her that the bottle was dangerous, the only label on it was the word "Phenol" The bottle was on the shelf, there were mixtures at one end of the shelf and liniments at the other The corporal knew that phenol was dangerous and a poison, he had not included it among the dangerous drugs which were locked away under his charge in the medical inspection room The coroner asked a medical witness whether he would expect phenol to be left out on a shelf available for nurses or anybody else to administer The witness replied in the negative but it is probably not the usual practice *to lock up the disinfectants constantly* required for sterilising instruments and dressings, with those potent drugs, dangerous in small doses, which are intended to be taken by the mouth According to the witnesses there was no general right to walk in and out of the dispensary *unless on business, and no nurse* had any authority to give medicine except under doctor's orders or on a prescription The bottle had no corrugated sides to distinguish it *as containing a poison*, though there was some corrugation on the bottom

The corporal said he had brought the bottle with him when he came to the post, he had no instructions about labelling poisons, he was not supplied with labels, but some had been obtained from an outside source He was a Nursing Orderly, class 3, trained by the R A M C He seems to have had no responsibility for this regrettable incident This was not a case of the absent-minded taking of one bottle in mistake for another, death was apparently due to a nurse not knowing that phenol is carbolic acid and is not intended to be administered to the patient by the mouth, whether for a cold or any ailment The coroner held that there had been negl but not culpable negligence of a criminal kind thought that the attention of the highest a should be drawn to what had occurred

Royal Sanitary Institute

Dr J E Gordon, professor of preventive medicine and hygiene at Harvard University, who is in charge of the American Red Cross Harvard Field Hospital in this country, has been elected an honorary fellow of the institute

Honours

American Congress of Physical Therapy has awarded a key to President Franklin D Roosevelt, in appreciation long interest and support of the medical fight against le paralysis Keys have also been given to Dr William attending physical therapist at Mt Sinai hospital, York, and to Lieut-Colonel W S C Copeman, y secretary of the British Rheumatism Association, ecognition of his development of a physical therapy tion in the battle field

Times Picayune loving cup for 1940 has been presented Rudolph Matas of New Orleans "in recognition of his of unselfish service to his fellow men"

for the Day

Ministry of Health and the Board of Education have ed a joint circular (Nos 2535 and 1573 of the respective stries) advising local authorities how to speed up the vision of day nurseries and play centres for the children women taking jobs But it points out that the greatest tribution to the task of dealing with these children must me from the stay at home women of the district, who must ide between them the duty of looking after the children those at work. The names of women willing to work if ir children are cared for, and of women willing to share the care of the children should be sent to the local authori- s and, with the help of voluntary organisations, the two oups should be put in touch with each other and helped in king friendly arrangements about the children which may they wish be extended to children of school age The cular stresses that it is the duty of the welfare authority set up a central office to act as a liaison between the mothers d the volunteers No more than three children should cared for in an ordinary working class home and health itors should pay special attention to these guest children robably the women will prefer to make their own arrange ents about payment but if need be the Government are ady to offer financial help under the scheme of daily guard- ns which is being administered by the regional controllers the Ministry of Labour It is described in their leaflet D L 67 revised) Forms of application for registration a daily guardian can be obtained at the local office of the inistry In addition to whatever weekly sum the mother rranges to pay to the guardian herself the state will pay 4*s* week for each child under five cared for on four days or more, nd 2*s* a week for each child for less than four days An pplication for this payment must be signed by both mother nd guardian

Public Health

From the Annual Reports

HENDON

HERE Dr A Fairgrieve Adamson reports an increase n infantile mortality from 34 to 54, largely due to high tality from respiratory diseases, which was spread venly throughout the year and not limited to the first uarter Dr Adamson says "at no time were the helters used to their full capacity, most persons pre- erring to remain in their own houses or to use shelters of he Anderson or other types" This seems to be usual n the towns of the outer ring of the metropolis

BOOTLE

This county borough, according to Dr F T H Wood's eport, had an estimated population of 67,760 in mid-1940, a reduction of 9010 from the 1931 census In stimating civil populations, those in the services of the Crown are excluded, and since these now number several millions, all estimated civil populations are artificially lowered, and since men and women in the services are of ages at which death is exceptional all death-rates are artificially exalted In Bootle the recorded death-rate was 17 3, against 12 4 in 1939, and the birth-rate 22 5, the highest rate since 1932, against the England and Wales rate of 14 6 Infantile mortality was 80 against 65 in 1939 The increase in infant deaths was mainly due to respiratory diseases in the first quarter of the year

ILFRACOMBE

In contrast to these industrial cities Dr D C Adam tells us that Ilfracombe had a birth-rate of 9 5, a corrected death-rate of 8 4, a tuberculosis mortality of 0 59 and an le mortality of 50 There was only one maternal h but th [illegible] aternal mortality of 9 71 The estimated population was 10 160 There were 96 notifications of scarlet fever, which is high for such a small population, but there was no death from the disease The negligible fatality of scarlet fever throughout the country since the start of the war is noteworthy

STAFFORD

Dr D H Binks in his report for this borough remarks that the corrected death-rate of 11 7 was above the ten years' average "probably due to the exclusion of the young members of both sexes who are now in the Services" There is another reason for an apparent rise in the death-rate which applies to all places which have been reception areas since the beginning of the war The rate is in fact based on the mid-year population of 35,320 In the reception areas the numbers of evacuees steadily fell during the first part of 1940 when all was quiet but rose rapidly when the war spread to Britain, so the average population of the year was higher than the mid-year estimate This makes all the vital-statistic rates based on the latter artificially high Dr Binks calls attention to the effect of the war on housing in reception areas—suppression of clearances and of building, and the temporary reconditioning of houses condemned or ready for condemnation After the war the badly destroyed towns must have first claim on the building industry, but the state of the towns which have not suffered from air-raids must be kept in mind

Infectious Disease in England and Wales

WEEK ENDED DEC 6

Notifications —The following cases of infectious disease were notified during the week smallpox 0, scarlet fever, 1324, whooping-cough, 1725, diphtheria, 1103, paratyphoid, 8, typhoid 17, measles (excluding rubella) 667, pneumonia (primary or influenzal), 979, puerperal pyrexia, 178, cerebrospinal fever, 132; poliomyelitis, 14, encephalitis lethargica, 8, dysentery, 165, ophthalmia neonatorum, 83 No case of cholera, plague or typhus fever was notified during the week

The number of civilian and service sick in the Infectious Hospitals of the London County Council on Dec 3 was 1346, including scarlet fever, 157 diphtheria 301 measles, 37, whooping cough, 477, enteritis, 52, chicken-pox, 46 erysipelas, 33, mumps, 17 poliomyelitis, 5, dysentery, 8, cerebrospinal fever, 11, puerperal sepsis, 18, enteric fevers 17, malaria, 1, other diseases (non infectious), 76, not yet diagnosed, 90

Deaths —In 126 great towns there were no deaths from scarlet fever, 1 (0) from enteric fevers, 1 (0) from measles, 6 (1) from whooping-cough, 27 (1) from diphtheria, 28 (1) from diarrhœa and enteritis under 2 years, and 29 (1) from influenza The figures in parentheses are those for London itself

Cardiff reported 1 death from an enteric fever

The number of stillbirths notified during the week was 177 (corresponding to a rate of 37 per thousand total births), including 14 in London

Births, Marriages and Deaths

BIRTHS

LIGHTWOOD —On Dec 19, at Gerrards Cross, Bucks, the wife of Dr Reginald Lightwood—a son

PARNELL —On Dec 15 in London the wife of Dr R W Parnell—a daughter

SWAIN —On Dec 14, at St Albans, the wife of Dr R H A Swain—a son

MARRIAGES

CALDWELL—DUNBAR.—On Dec 20 at Burnham Bucks, Kenneth Peter Somerville Caldwell M B to Dorothy Anderson Dunbar

KEITH—PAKEMAN —On Dec 19 in London John Stobart Keith to Evelyn May Pakeman, M B

STAFFORD CLARK—STEWART —On Dec 16 at Mundham Sussex, David Stafford Clark, M.B squadron leader R.A F V R, to Dorothy Stewart (*née* Crosley Oldfield)

DEATHS

BEGG —On Dec 17 Alexander Clarke Begg O B E M D Edin, M B Lond, consulting physician to the Swansea Hospital

FLEMMING —On Dec 19, at Upper Basildon near Reading Percy Flemming M D Lond, F R C S, aged 78

GRAY —On Dec 20 at Epsom James Hugo Gray, M D Adelaide professor of anatomy at St Mary s Hospital Paddington aged 32

HARRISSON —On Dec 15 at St Neots Hunts Ernest Henry Harrisson M A M D Camb, aged 64

STABB —On Dec 19, at Torquay, E Carthew Stabb, F R C S, aged 78

The fact that goods made of raw materials in short supply owing to war conditions are advertised in this paper should not be taken as an indication that they are necessarily available for export

Notes, Comments and Abstracts

TYNESIDE PROSPECT

IN the fifth reprint and second edition, since 1940, of his survey of social conditions on Tyneside,[1] Mr D M Goodfellow, Ph D, has done more than repeat the facts about high infant and tuberculosis death-rates, and the other penalties of the years of depression which make such bitter reading, he has added two new chapters about regional planning and in doing so lays bare a tangle of conflicting values The Royal Commission on Local Government found great disparity in the health services throughout the Tyneside area Some of the poorest towns make the best efforts to improve their social services, though they can only do so by taxing their citizens and thus increasing poverty, some towns reach high standards in services which in a neighbouring town may hardly exist, and in many services the national standard is only reached in Newcastle itself Thus the social services as a whole do not correspond to the needs of the area To overcome such disparities the commission proposed the establishment of a new region, to consist of industrial Tyneside plus Northumberland county, and the formation of a new municipal borough to include the whole of industrial Tyneside Dr Goodfellow, though he favours the regional idea, insists that to believe the mere advent of regions would automatically solve all problems is a bad mistake To weld Tyneside into one with the county might lead to over-emphasis on agricultural interests, and hence to disparities of social services within the region as wide as any now found on Tyneside Moreover it would divide industrial Tyneside from its natural partner, Durham, with which it has close economic and cultural ties The commission, indeed, suggested that the new region might later include Durham, but Dr Goodfellow believes that it would be better if it did so from the start, if only because of Durham's considerable achievements in social services which would help to serve as a pattern and encouragement to Tyneside The county of Durham is at once smaller than Northumberland and much more heavily industrialised, its inclusion in the region would not introduce the preponderance of agricultural interests to be feared from linking Tyneside only with Northumberland The new Tyneside borough, in the view of the commission, should have powers corresponding to those exercised by a municipal borough Thus it would have control of drainage, sewerage, street-scavenging, the inspection of slaughter-houses and the maintenance of minor roads, but it seems likely that the maternity and child-welfare services would come under the regional authority There is a chance, Dr Goodfellow believes, that such limited scope as these powers offer might fail to attract the right type of councillor Housing, too, would be a special problem Some Tyneside towns have attacked housing troubles with great tenacity and success in the past twenty-five years—Felling council, for example, have turned their overcrowded slum-ridden district into one of the best and most beautiful garden cities in the country Councils which carry out big housing schemes become big landlords and big employers of labour and they have an important share in town planning and industrial development, citizens begin to visit the council offices to pay rents and discuss repairs, and thus get to know the officials and councillors It seems to them proper that the council should control the schools, and they feel they have a personal share in their own schools and their own municipal housing If a new great municipal borough is formed it will take over the council houses of all districts, and this keen sense of local responsibility will be lost More disrupting still, housing will come under an authority which has no means of coordinating it with town and industrial planning, public-health services or education It might be better, Dr Goodfellow feels, to invest all powers in the regional authority, provided the region included both Northumberland and Durham with Tyneside in the middle Such a north-eastern region could take united decisions on industrial planning and uniform development of social services on lines suited to both agricultural and industrial districts, and coul ensure equitable treatment by the national exchequer Moreover a really clever authority might find means t foster and maintain a sense of local responsibilit among the citizens of its various districts, and th would be something new in large-scale local governmen

GOOD ENGLISH EARTH

NOW that we must deck our table from our own field agriculture is coming into her own again, and long m we all enjoy it She has been a struggling industry t long *England and the Farmer* (Editor H J MASINGHAM London B T Batsford Pp 152 10s 6d a timely symposium of authoritative opinion, deserv to be widely read and pondered In a vigorous intr duction, Mr Massingham pleads for a return to t small mixed farm, to farming for subsistence rather tha by a prostitution of scientific knowledge, for big profi *This note is stressed by other writers, notably* Dr L Picton in his provocative article on diet and farming which he contrasts the difference between the fo produced by the sea and the land The sea is se manuring "All the wastes of the sea remain in t sea Its cycle of fertility is established a its by-product is vigour", but food from the la nowadays is largely produced by means of chemi applications with consequent loss of quality and a v legacy of defective nutrition and subnormal healt There is a quiet dignity about this book, and the ma beautiful photographs enhance its charm

MEDICAL DIRECTORY FOR 1942

PUNCTUAL as ever in its appearance the new directo contains 65,394 names, being 1090 more than in the 19 issue It is easy to believe that 300 fewer doctors a living in London, not so easy to guess the significance 500 more names in the Scots and Irish sections But w must not in these days inquire too closely where o colleagues are working, we must try to be content wi *having at all events an up-to-date box number* Oth signs of the times are the occasional heading "emergen hospital," and the list of 962 temporarily registere practitioners (not included in the figures already give Among the universities from which these have qualifie to mention a selection from the first column, a Bratislava, Toronto, Oklahoma, Cracow, Prague, Vermon *Wurzburg, Lwow, Ohio, Vienna, Warsaw,* Berli Medicine indeed has joined hands across the wor With sympathetic regret we note that the resetting i new and clearer type has made no further advance Th price of the directory remains at 63*s*, from J & Churchill
